$Document\ MOP7.14-7^{th}\ Edition\ of\ the\ Conservation\ Status\ Report\ (CSR7)$ Annex 1 - Population sizes and trends of waterbird populations listed on Table 1 of the AEWA Action Plan

| order Family Species Population | Discontinued | Size - year | Size | Size estimate quality | Size references | Trend - year | Trend | Trend quality | Trend references | 1% threshold | 1% yearset | Notes |
|--|--------------------|-------------------|----------------------|-----------------------------|--------------------|--------------------|----------|------------------|-------------------------------|-----------------|---------------|-------------------------------|
| Anseriformes | | | | | | | | | | | | |
| Anatidae | | | | | | | | | | | | |
| Dendrocygna viduata (Whi | te-faced Whistling | -duck) | | | | | | | | | | |
| West Africa (Senegal to Chad) | | 1999 - 2008 | 600,000 - 700,000 | Expert opinion | [R642] [R648] | 2006 - 2015 | STA/INC? | Reasonable | [R1548] | 6500 | 2018 | [P1351] [S8678] [T6868] |
| Eastern & Southern Africa | | 1991 - 2014 | 500,000 - 800,000 | Expert opinion | [R1371] | 2006 - 2015 | STA/INC? | Reasonable | [R1548] | 6300 | 2018 | [P1352] [S9112] [T6869] |
| Dendrocygna bicolor (Fulve | ous Whistling-duc | k) | | | | | | | | | | |
| West Africa (Senegal to Chad) | | 2006 - 2014 | 20,000 - 50,000 | Expert opinion | [R1371] | 2006 - 2015 | UNC | Poor | [R1548] | 320 | 2018 | [P1340] [S8676] [T6866] |
| Eastern & Southern Africa | | 2001 - 2001 | 150,000 - 350,000 | Expert opinion | [R190] | 2006 - 2015 | DEC? | Poor | [R1548] | 2300 | 2018 | [P1341] [S8677] [T6867] |
| Thalassomis leuconotus (V | /hite-backed Duck | k) | | | | | | | | | | |
| leuconotus, West Africa | | 2006 - 2006 | 1 - 500 | Best guess | [R192] | 1982 - 1992 | DEC | Poor | [R1371] | 1 | 2018 | [S9113] |
| leuconotus, Eastern & Southern Africa | | 1990 - 1990 | 10,000 - 25,000 | Best guess | [R115] | 2006 - 2014 | DEC | Reasonable | [R1548] | 250 | 2018 | [S9132] |
| Oxyura maccoa (Maccoa D | uck) | | | | | | | | | | | |
| Eastern Africa | | 2001 - 2005 | 1,500 - 1,500 | Expert opinion | [R1509] [R190] | 2006 - 2015 | DEC | Poor | [R1559] | 15 | 2018 | [P1373] |
| Southern Africa | | 2000 - 2005 | 7,000 - 8,250 | Expert opinion | [R1509] | 2006 - 2011 | DEC | Reasonable | [R1548] [R1585] | 75 | 2018 | [T6981] |
| Oxyura leucocephala (Whit | e-headed Duck) | | | | | | | | | | | |
| West Mediterranean (Spain & Morocco) | | 2006 - 2012 | 2,500 - 3,500 | Expert opinion | [R1549] [R1548] | 2000 - 2012 | STA | Reasonable | [R1548] [R1549] [R1586] | 25 | 2018 | [P1367] [S9051] [T6978] |
| Algeria & Tunisia | | 2011 - 2014 | 2,500 - 2,500 | Census based | [R1548] | 2006 - 2015 | STA/FLU | Reasonable | [R1548] | 25 | 2018 | [P1368] [S8899] [T6982] |
| East Mediterranean, Turkey & South-west Asia | | 2013 - 2016 | 18,000 - 21,000 | Expert opinion | [R1569] | 2006 - 2015 | DEC? | Poor | [R1548] | 200 | 2018 | [S9052] |
| Cygnus olor (Mute Swan) | | | | | | | | | | | | |
| North-west Mainland & Central Europe | | 2000 - 2013 | 173,000 - 243,000 | Expert opinion | [R1549] | 2000 - 2015 | INC/STA | Good | [R1549] [R1548] | 2000 | 2018 | [P1468] [S8866] [T6872] |
| Black Sea | | 1990 - 2012 | 49,000 - 72,000 | Expert opinion | [R1549] | 2000 - 2015 | STA? | Reasonable | [R1548] [R1549] | 590 | 2018 | [S8867] [T6873] |
| West & Central Asia/Caspian | | 1987 - 2015 | 250,000 - 250,000 | Best guess | [R1569] | 2006 - 2015 | INC? | Reasonable | [R1548] | 2500 | 2018 | [S8918] |
| Cygnus cygnus (Whooper | Swan) | | | | | | | | | | | |
| Iceland/UK & Ireland | | 2015 - 2015 | 34,000 - 34,000 | Census based | [R1562] | 2005 - 2015 | INC | Good | [R1562] | 340 | 2018 | [P1552] [T6875] |

Notes

- P1351 These populations were treated as a single larger population WPE1. (WPE2)
- S8678 Trolliet, B. In litt. 2011.. Numbers counted simultaneously in West Africa exceeded 400,000 in 2008
- T6868 Long-term trend is stable.
- P1352 These populations were treated as a single larger population WPE1. (WPE2)
- S9112 Numbers clearly more than previous lower estimate of 100,000. This figure is based on 300,000 400,000 for Eastern Africa, up to 100,000 in eastern Central Africa and 200,000 -300,000 in Southern Africa.
- . T6869 Long-term trend is also stable

- P1341 These populations were treated as a single larger population WPE1. (WPE4)
- S8677 Patchy IWC data does not permit to improve the estimate of this rather nomadic species.
- T6867 2000-2015: 0.8463 (SE 0.0441) steep decline.
- S9113 No IWC records.
- S9132 IWC counts may reach ca. 1,000 for whole range. No significant new information for this rather thinly-spread species.
- P1373 These populations were treated as a single larger population WPE1. (WPE2)
 T6981 IWC trend analysis suggest a short-term decline, but the long-term trend is still an increase (Wetlands International 2017). This decline is also confirmed by the SABAP2 data (Underhill & Brooks 2016).
- P1367 These populations were treated as a single larger population WPE1. (WPE2)
 S9051 120-318 pairs breeding and 1,562 individuals wintering in ES (BirdLife International 2015). Numbers wintering in Morocco are smaller: the max. so far was 642 in in 2015 (Wetlands International 2017 based on data from GEPROM).
- T6978 IWC trend analysis shows strong long-term fluctuations (Wetlands International 2017).
- P1368 These populations were treated as a single larger population WPE1. (WPE2)
- S8899 Yearly count totals from 2011 to 2014 were: 1,713, 2,029, 1,204 and 2,585 individuals
- T6982 Long-term increase.
- S9052 Revised estimate is based on numbers recorded in Kazakhstan (18,049-20,859 individuals).
- P1468 These populations were treated as a single larger population WPE1. (WPE2)
- S8866 57,821 80,972 pairs in AT, BA, BE, BY, CH, CZ, DE, DK, EE, FI, FR, HR, HU, IT, LI, LT, LU, LV, NL, NO, PL, SE, SI & SK
- T6872 Trends based on both breeding (BirdLife International 2015) and wintering (Wetlands International 2017) data show that the rate of decline has slowed down or even stabilised.
- S8867 16,257 23,992 pairs in AL, BG, GR, MD, MK, RO, RS, RU, TR & UA
- T6873 Breeding (BirdLife International 2015) and wintering (Wetlands International 2017) data indicate an overall stable trend in the short-term following earlier declines.
- S8918 See CSR 6 and Sheldon (2017).
- P1552 Sometimes ascribed to "islandicus"
- T6875 Continued increase since 1995.
- S8869 More than 120,000 (based on >30,000 estimated for Germany) in addition to a total of 90,000 birds counted.
- T6876 Trend based on breeding data shows continued increase albeith the short-term trend indicates a slower increase than the long-term one (BirdLife International 2015). This is similar to the results of the trend analysis based on IWC counts (Wetlands International 2017), which shows stablisation of numbers between 2006 and 2015. The results of the 2015 International Swan Census are not yet available at the time of writing.
- \$8475 5-year-mean of IWC counts at site level add up to is 13,953 for the period of 2008-2012. Annual count totals between 1,773 and 6,443 individuals during the same period.
- S8476 See Scott & Rose (1996) for details. 16,255 inidividuals in January 2013.
- T6878 There is no evidence of continued decline after 2000, but the main wintering areas in the northern part of the Caspian are not monitored.
- P1612 Considered separate from Cygnus columbianus, following Birdlife 2012 review.
- S8870 Including a reasonable estimate of 5,500 birds in Germany in addition to what was counted.
- T6879 Agricultural areas migh be under-represented in the sample especially in DE.
- P1613 Considered separate from Cygnus columbianus, following Birdlife 2012 review.
- S8871 IWC count totals for 2012-2015 with data from Vaneguwe et al. (2016) for 2016. Their radio-telemetry studies raise questions concerning the population definitions for this species.
- T6880 IWC trend analysis based on data only from TR but also the IWC count totals taking into account data from all other countries show very strong increase in the local wintering population (Wetlands International 2017). However, the population assignment of the birds wintering in the East Mediterranean is waiting for clarification from reviewing the results of telemetry and neck banding studies.
- T6896 +0,6% p.a.
- S8889 Five-year-mean
- T6898 Continued increase since 1993 until 2012. Declining since then. The long-term trend is stil positive.
- T6893 +3,9% p.a.
- T6894 +4,4% p.a.
- T6895 +9.9% p.a.
- \$8890 Fox & Leafloor (in prep.) estimated the numbers to be between 50,000 and 100,000 accepting both the lower wintering and higher, strongly contested, non-breeding counts. However, Cuthbert & Aarvak (2017) reported only 50,100 (28,100-72,600) individuals from the staging areas in Kazakhstan using proper field methodology and statistical analysis and which is consistent with wintering numbers. Therefore, this estimate is adopted here.
- T6899 The short-term population trend is uncertain because of the inadequacies in population estimates (see BirdLife International 2017 for details), Although, BirdLife International maintains the decreasing trend assessment, for the short-term this is not supported by anything else 5-10% decline reported from RO. The short-term trend is stable, fluctuating or unknown in eight of the twelve European range state of the species and increasing in another two (BirdLife International 2015). RU has even reported 80-100% increase of the breeding population between 1980 and 2012.
- S8880 Five-year-mean for 2007-2016.
- T6890 -1.5% per annum calculated based on WWT (2017)
- S8881 Point estimate is based on extrapolation from earlier estimate.
- T6891 Increasing trend both in the long- and short-trend confirmed by breeding population estimates (BirdLife International 2015), general IWC counts (Wetlands International 2017) and specialised goose counts (Fox & Leafloor in prep.).
- \$8882 14.304 20.094 pairs (i.e. 43.000 60.000 individuals) in AL, AT, BY, CH, CZ, EE, FI, HR, HU, IT, LT, LV, PL, SK, This tallies well with the previous estimate based on IWC counts in 2009-2012. However, count totals reached 70,000 birds in 2013. Fox & Leafloor (in prep) produced an index based estimate of 100,000 individuals, but this migh be an overestimate.
- T7167 Trend 1988-2012: +5.66% p.a., 2003-2012: +1.19% (Nagy et al. 2014). Fox & Leafloor (in prep). estimated +6.8% for 1995-2008.
- S8883 This estimate tallies well with the estimates of 8,247 14,144 pairs (i.e. 25,000 42,000 individuals) for the breeding population ein the Black Sea region without RU (BirdLife International 2015). The IWC count totals are always under 12,000 individuals in the last 10 years.
- S8919 Cuthbert & Aarvak (2016) estimated c. 250,000 (177,700-320,000) individuals in Kazakhstan in the autumn of 2016. However, numbers from elsewhere in the region are not known.
- T6260 Trend 1988-2012: -17.7% decline. Longer term trend (1988-2012) is uncertain due to large number of missing counts. Trend is mainly driven by the declines in Iran.
- T6881 -6% p. annum
- P1800 Johanseni was considered no longer valid in WPE4 based on Burgers et al. (1991 Ardea 79: 307–316), Sangster and Oreel (1996 Dutch Birding 18: 310-316) and Heinicke (2008 Casarca 11: 53-75 and 2009 Wildfowl 59: 77–99) all questioned the validity of subspecies johanseni and Ruokonen and Aarvak (2011 Molecular Phylogenetics and Evolution 48: 554–562) found no support for its existence using mDNA analysis. Besides the genetic basis, there is also strong morphological and ecological evidence that Bean Geese breeding in western Siberian taiga belong to subspecies fabalis (e.g. Burgers et al. 1991, Mooij and Zöckler 1999 Casarca 5: 103-120, Heinicke 2009). Instead a separate population of fabalis considered to winter in Central Asia and this view is adopted in the AEWA SSAP for Taiga Bean Goose. However. A. f. johanseni is still recognised by the HBW/BirdLife International, the taxonomic reference of AEWA, and other global authorities such as Clements 6th edition (version 6.9 incl. 2014 revisions), Howard and Moore 4th edition and IOC World Bird Names, version 4.04.
- S9114 Practically disappeared as winter visitor in Kyrgyzstan, no large numbers reported since mid 2000s.
- T6883 +2.8% p. annum
- T6884 Continued increase since the 1970s which has accelerated since the early 2000s.
- S9046 Estimate updated based on the latest population estimate mentioned in the reference.
- T6885 +0.8% p. annum. After long-term increase the population appears to have stabilised in recent years.
 S9053 Jongejans et al. (2015) reported an average estimate of 139,000 individuals for the period of 2008-2012. However, the average IWC January count totals for 2011-2015 even without any accounting for missing counts have reached 167,000 individuals with 252,781 and 178,277 individuals in 2012 and 2013 respectively (Wetlands International unpublished data). As this
- might be caused by influx from other populations, the five-year mean is used as a population size estimate.

 T6254 Trend 1988-2012: +9.66% p.a., 2003-2012: 5.24% p.a. (Nagy et al., 2014). Trend 1958-2009: +7.7% p.a. Trend 1995-2009: +2.9% p.a. (Fox et al., 2011).
- \$8877 400,000 individuals were counted in January 2017 in Bulgaria. This number is not yet included into the estimate because it is unclear whether it was just an influx from the Central European population.
- T6887 1988-2012: +1.4% per annum.
- \$9054 24,030 individuals reported from Uzbekistan in January 2017. An additional 1,350 was reported from Iran (Wetlands International 2017). This indicates that earlier figures were an underestimation. Therefore, this figure is adopted as a new minimum estimation.
- T6256 Fairly sporadic IWC data indicate that the decline of this population continues. Numbers counted at the Gyzylagach Nature Reserve, Azerbaijan, gradually decreased from 11,952 in 2003 to 0 in 2010-2012. At Lake Aggyol, Azerbaijan, numbers decreased from 1,450 in 2004 to 900 in 2012. National totals for Iran decreased from 2,008 in 2001 to 287 in 2012.
- T6886 Following an increase from 1983 to 1999, the population is declining with a rate of 2.8% p annum approaching the levels in 1983.
- P1878 Separated into Fennoscandia/Eastern Mediterranean and N Europe & W Siberia/Black Sea & Caspian populations in WPE5.
 P1879 In WPE4 this population belonged to one single population, N Europe & W Siberia/Black Sea & Caspian. This population was separated into three populations following Jones et al. (2008) into the following populations: - Fennoscandia/Eastern Mediterranean: not including the supplemented/reintroduced population in Swedish Lapland/Netherlands - W Siberia/Caspian & SW Asian - Supplemented/Reintroduced population in Swedish Lapland/Netherlands
- T6888 Significant long-term decline over 7.5 generations. By 2016, the population has recovered to the 1990 levels.

- S9055 The two Palearctic populations are separated based on their breeding grounds and their wintering areas overlap. 12,000-33,000 breeding pairs are estimated on GL and IS (BirdLife International 2015). Wintering numbers in GL, IS, IE and the UK are estimates to be 163,000-1,200,000 individuals, both much higher than the upper limit of the estimate of 99,000 individuals calculated from the estimated breeding population. However, the wintering estimate for GL ranges between 100,000 and 1,000,000 (Merkel et al., 2002) and birds wintering around GL might come from both from West Sibera and Canada.
- S9056 Skov et al. (2011) estimated the number of Long-tailed ducks at 1.486,000 individuals in the Baltic Sea based on surveys and modelling in 2007-2009. BirdLife International (2015) has estimated the European wintering population to be around 1,300,000 2,600,000 individuals without Greenland, Iceland and the UK. Their breeding population estimate for Scandinavia and European Russia is 325,900 411,800 pairs (i.e. 978,000 1,235,000 individuals), but this does not include birds breeding in West Siberia. Considering the uncertainties and gaps in summing up the national estimates, the AEWA SSAP (Hearn et al. 2015) for the species has retained the current estimate until the results of the coordinated Baltic Seaduck Survey of January 2016 are available.
- T7169 Hearn et al. (2015) have reviewed available evidence of decline. IWC-based trend analyses (HELCOM 2017, Wetlands International 2017) suggest that some recovery is taking place since the mid-2000s, but the JWGBIRD (Markones in litt) expressed doubts concerning the representativity of land-based counts and reassessment of the trend is pending until the availability of the 2016 January Coordinated Baltic Seaduck Survey.
- S9058 The estimate is based on wintering numbers from Ekroos et al. (2012). The CSR6 estimate has erroneously included 46,500 wintering birds from Norway, which should have been allocated to the Norway & Russia population. Ekroos et al. reported 276,850 breeding pairs (i.e. c. 830,550 individuals) for DE, DK, EE, FI, NL, SE. BirdLife International (2015) reports 197,305 293,011 breeding pairs and 575,006 631,871 wintering individuals. The difference in wintering numbers is mainly caused by the hugen difference in numbers reported from DK: 500,000 individuals in Ekroos et al. (2012) and 140,000 individuals in BirdLife International (2015) for the same year 2008.
- T6958 IWC data shows increase/recovery after 2010 and a very fluctuating but overall stable long-term trend (Wetlands International 2017). See the discussion of these results in comparison with Ekroos et al. (2012) and BrdLife International (2015) in Wetlands International (2017).
- \$9059 New estimate for the NO population is 150,000 pairs. 50% of the RU population is 20,000-25,000 pairs. This yields a total estimate of 510,000-525,000 individuals (BirdLife International 2015).
- T6959 2006-2015: 1.0040 (SE 0.0012). The long-term trend (1982-2015) is 0.9813 (SE 2e-04).
- S9060 20,000-27,500 pairs (BirdLife International 2015). The Norwegian Polar Institute (2017) reports 13,500-27,500 pairs on Svalbard. The current abundance of the common eider on Novaya Zemlya is unknown (Krasnov et al. 2016).
- T7169 Increased in Franz Joseph Land (M. Gavrilo in litt. 2014). The Norwegian Polar Institute (2017) reported data that indicates a 2% p annum rate of decline for the period of 2007-2016, with a major crash in 2013 and 2016. The long-term trend (1982-2016) is a 0.6% p.a. decline, which can be interpreted as stable but would be equivalent to 34% decline over 7.5 generations. However, this is based on only one location even if that represents 15-22% of the estimated Svalbard breeding population. The trend quality is assessed as being poor because the trend is assumed based on partial information.
- S9061 Coordinated aerial count of wintering Steller's Eider was conducted in Norway and Russia in 2009.
- T6961 Numbers found during two surveys in 1994 and 2009 (Nygard et al. 1995, Aarvak et al. 2012) were similar. Baltic subpopulation continues decreasing (BirdLife International 2015, HELCOM, 2017). However, JWGBIRD (Markones in litt) expressed doubts concerning the representativity of land-based counts which concerns in case of this species only the smaller Baltic subpopulation.
- T6993 This trend is based on two major Baltic-wide surveys (see details in Dagys 2017). However, both the short- and long-term wintering trends are fairly uncertain based on the national trend estimates reported by BirdLife International (2015). The short-term (2000-2012) national wintering trends were considered to be stable in most countries except LT, DK and GB (declining), SE, NO, IE (unknown). The long-term (1980-2012) wintering trends were considered to be negative in LV, LT, DE, DK and FR, stable in EE, NL, BE and unknown in PL, SE, NO and IE. Flyway level analyses of trends in wintering numbers based on IWC data (Wetlands International 2017, HELCOM 2017) also show declines between the early 1990s and the 2000s, but they also suggest a recovery from the second half of the 2000s. However, the JWGBIRD (Markones in litt) expressed doubts concerning the representativity of land-based counts and the reassessment of the wintering trend is pending until the availability of the 2016 January Coordinated Baltic Seaduck Survey. Trends in breeding numbers also difficult to assess but the reported long-term breeding trends (1980-2012) were thought to be negative in all countries, while the short-term trend (2000-2012) was negative in all countries except SE, where stable, and RU, where unknown (BirdLife International 2015). Considering the uncertainties concerning the most recent trends (i.e. 2006-2015), the long-term trend is reported.
- T6964 The short-term trend is uncertain, while the long-term trend is negative based on both the breeding (BirdLife International 2015) and the wintering numbers (Wetlands International 2017).
- P2372 Melanitta nigra and americana are now generally considered as different species.
- S9064 BirdLife International (2015) estimated 682,000 805,000 individuals wintering in Europe. 5,000 10,000 individuals can be also added for Morocco (Wetlands International 2017).
 Petersen (in litt. 2014) has argued that the population could be up to 1.2 million birds based on simultaneous counts from Germany and Denmark, but this should be first confirmed by the analysis of the results of the Januar 2016 Coordinated Baltic Seaduck Survey.
- T6963 The European breeding trend is unknown in the short-term because the trend of the large RU population (93%) is unknown. The long-term trend is stable. The short-term trend based on national trends in wintering numbers is increasing and the long-term trend is unknown or fluctuating for most countries except BE, LV and ES all with small populations, thus cannot be assessed (BirdLife International 2015). HELCOM (2017) reported increasing trend both for the long- and the short-term, but the JWGBIRD (Markones in litt) expressed doubts concerning the representativity of land-based counts and reassessment of the trend is pending until the availability of the 2016 January Coordinated Baltic Seaduck Survey. Wetlands International (2017) reported an uncertain trend.
- S9065 The annual count total was around 140,000-168,000 individuals between 2011-2015 (Wetlands International 2017), but Delany and Scott (2006) argued that wintering numbers represent a significant underestimation and breeding numbers should be used instead. The sum of the national breeding population estimates for UK, NL, DE, DK, AT, NO, SE, FI, EE, LV, LT, PL is 287,882-401,236 pairs (BirdLife International 2015). According to Delany and Scott (2006), 25% of the estimated 200,000-220,000 pairs in RU (BirdLife International, 2015) can be also added to this population. This yields an estimate of 990,000-1,370,000 individuals which is roughly the same as the existing estimate.
- T6965 The IWC trend analysis indicates a stable trend in the short-term (Wetlands Inernational 2017). BirdLife International (2015) reports negative trends for the breeding populations. It also reports declines in wintering numbers on the SW edge of the range and increases in the NE one. The long-term trend is stable in breeding numbers and increase in wintering ones.
- \$9066 The avarege count total was 3,500 8,700 individuals between 2011 and 2015 (Wetlands International 2017). The sum of the national estimates for wintering birds in IT, SI, HR, BA, ME, AL, MK, HU, RS, SK and GR is 30,000 47,179 individuals (BirdLife International 2015). The maximum population estimate is based on the estimate Delany and Scott (2006) have derived from the RU breeding population. [However, it is unclear from their description how this figure was derived and how it adds up with the estimates for the other populations considering that the minimum estimate for European RU is 200,000 breeding pairs, i.e. 600,000 individuals. Having already allocated 25%, i.e. 150,000 individuals to the NW & Central European population, adding all the 200,000 individuals to the Adriatic population and 60,000 individuals to the Black Sea population still leaves 190,000 unallocated individuals.]
 T6966 According to BirdLife International (2015) national wintering population trends are decreasing in RS and AL, stable or unknown in other countries and increasing in SK, which
- T6966 According to BirdLife International (2015) national wintering population trends are decreasing in RS and AL, stable or unknown in other countries and increasing in SK, which compensates for the losses in those other countries. The IWC trend analysis reports a steep decline (Wetlands International 2017), but recent data from both SK and RS are misising and values for these countries were mainly imputed in the short-term. Therefore, the IWC trend is considered to be less certain.
 \$9067 The IWC count totals were around 15,000 60,000 individuals during 2011-2015 (Wetlands International 2017), i.e. the maximum count has reached the population estimate Delany
- S9067 The IWC count totals were around 15,000 60,000 individuals during 2011-2015 (Wetlands International 2017), i.e. the maximum count has reached the population estimate Delany
 Scott (2006) derived from the breeding population estimate for RU in BirdLife International (2004), despite the fact that countries with important populations of the species, such as UA,
 were not counted during this period. The sum of the national wintering population estimates is 16,000 45,000 individuals (BirdLife International 2015).
- T6967 IWC trends are uncertain but show positive tendency both for the long- and the short-term (Wetlands International 2017). These agree with the wintering and breeding trends reported by BirdLife International (2015) for the region.
- P2386 WPE4: E & W Coast populations may merit separate treatment.
- S8568 Sklyarenko et al. (2008) set the 1% threshold for this population at 270 individuals, which means a middle point of 27,000, which is probably more realistic than the 100,000-1,000,000 estimate of Delany & Scott (2006) and close to Scott & Rose (1996) estimate. This figure is close to the maximum count of 21,850 individuals in 2004 (Solokha, 2006) during a comprehensive survey in the Caucasus and Central Asia.
- \$9068 The IWC count totals were around 15,000-22,000 individuals between 2011-2015 (Wetlands International 2017). BirdLife International (2015) reported 24,000-38,422 wintering individuals and 6,135-12,565 breeding pairs (i.e. 18,000 38,000 individuals) based on national estimates between 2001 and 2012.
- T6969 Stable but statistically uncertain trend based on IWC data (Wetlands International 2017) which is also suggested by BirdLife International (2015) for the period of 2000-2012.
- \$9069 The annual IWC count totals were around 3,000 4,700 individuals during the period of 2008-2012. The peak IWC count was 29,338 individuals in Jan. 2005. BirdLife International (2015) reported 7,700 26,000 wintering individuals, which seems to be high compared to the 3,000 5,000 breeding pairs estimated for 50% of RU.
- T6970 1997-2015: 0.9551 (SE 0.0223). BirdLife International (2015) has also reported declines in the RU breeding population.
- S8571 The average annual count total was 1,304 during the period of 2008-2012. Sum of the site-level 5-year means is 3,963. Perrenou et al. (1994) based the current estimate on a large count at Kale Degizkul on the border of TM and UZ in 1986.
- P2408 Includes UK population. Split from NW Europe population in WPE2.
- \$9070 The IWC count totals were around 51,500-112,000 individuals between 2011-2015. The maximum count was 111,797 individuals in 2014. However, this species is not well monitored through on-shore counts. The sum of the wintering population estimates in AT, BE, DE, DK, EE, FI, FR, LT, LU, LV, NL, PL, SE, SI, SK, UK was 116,118-177,198 individuals and the sum of the national breeding population estimates in DK, EE, FI, IE, LT, LV, PL, SE, SK, UK, NO and RU (20%) is 58,843-92,313 pairs (BirdLife International 2015). This yields an estimate of 177,000-277,000 birds after rounding.
- T6975 BirdLife International (2015) reported declining trend in the short-term (2000-2012) and stable for the long-term (1980-2012). The decline is only reported from FI in the short-term and from FI and EE in the long one. The long-term IWC trend agrees with the one based on breeding numbers. The short-term one also shows some decline at the begining of the period but indicates some stabilisation and weak rebouncing.
- \$9071 7,290 9,745 pairs (22,000 29,000 individuals, 6,177 11,785 wintering birds (BirdLife International 2015). The IWC count totals were around 166-355 individuals between 2011-2015 (Wetlands International 2017).
- T6976 Results of IWC trend analysis are highly uncertain (Wetlands International 2017). BirdLife International (2015) reported stable trends of wintering populations in most countries except RS, MD where increasing. The trend is unknown in ME, GE, GR and TR. Also the breeding trend is increasing in all countries except in RO where the trend of the small breeding population is unknown.

International 2015). The IWC count totals were around 27,000-37,000 individuals between 2011-2015 (Wetlands International 2017). Possibly, the population size is substantially underestimated based on the wintering counts.

- T6972 The IWC trend analysis shows slow on-going decline from the mid-1990s following a strong overall incease (Wetlands International 2017). This contradicts the pattern based on breeding numbers reported by BirdLife International (2015) that indicates more positive short- than long-term trend.
- P2400 Split from NW Europe (win) population in WPE2
- \$9155 7,300-10-384 pairs (22,000-31,000 individuals) in the entire European RU and UA. Sum of national wintering population estimates is 3,968-6,680 individuals (BirdLife International 2015). The IWC count totals were around only 616-708 individuals between 2011-2015 (Wetlands International 2017).
- T6973 1985-2015: 0.9633 (SE 0.0143) steep decline, 2006-2015: 0.9526 (SE 0.0742) uncertain with a strong declining tendency
- S8574 The average IWC count total is 235 individuals for the period of 2008 and 2012, with a maximum of 892 in 2010. The sum of the site-level 5-year means is 829 individuals.
- T6974 Possibly significant long-term decline
- T6900 Long-term trend is possibly stable/fluctuating.
- T6901 Long-term trend is stable/fluctuating (MSI) or even increasing (TRIM) depending on the statistics used.
 \$9144 41,472-54,112 pairs in BE, CZ, DE, DK, EE, FI, FR, IE, IS, LT, LV, NL, NO, PL, SE, UK and 10% of RU (BirdLife International 2015). IWC count totals were around 157,000-240,000 individuals between 2011-2015 (Wetlands International 2017). Estimate of 250,000 individuals retained.
- S8893 The IWC count total has reached 260,000 in 2014 and it was also above 210,000 in 2012.
 S8523 The current estimate is based on Perennou et al. (1994) using data up to 1991. Large counts of 73,947 (1995), 78,138 (1996) and even 157,594 individuals (1999) continued in the 1990s. There is a marked decline even in the count totals adjusted for missing counts after 2005. The sum of the site-level 5-year-means for the period of 2008-2012 was 31,391 individuals. 30,369 individuals were also counted in 2013. However, counts are concentrated in IR, IQ and AZ and thousands of birds might be missed. Therefore, the revised estimate is 30,000-50,000 individuals.
- T6908 Significant long-term decline.
- S8891 Current count totals exceed the maximum estimate. New estimate is based on the earlier estimates and using the annual growth rate from the trend analysis. It shows a good fit with interim estimates.
- \$8892 13,470 20,523 pairs in AL, AM, BG, GE, GR, MD, RO, RU, TR, UA
- T6903 The trend assessment is based on the IWC data (Wetlands International 2017) shows a strong increase from 1990, which is well supported also by the count totals. This also agrees with the assessment by BirdLife International based on breeding numbers (2015). However, they reported small decline both for the short- and the long-term trend based on the assessment for TR. However, this was reported as a poor trend estimate by the country itself, therefore, the increasing trend suggested by other sources of data is retained.
- S8920 See CSR6 and Sheldon (2017). Cuthbert and Aarvak (2016) reported 53,000 individuals from Kazakhstan alone.
- T6904 The long-term trend shows a fluctuating pattern either due to genuine population changes or due to insufficient coverage.
- S8682 lack of new qualitative data or published reports to consider change in light of suspected decline as reflected by IWC data.
- T6905 The population is likely to fluctuate. Therefore, the long-term trend is reported.
- T6909 Both the raw count totals and the trend analysis (that takes into account of missing counts) suggest an increasing population in the short-term with large fluctuations, which supports Trolliet (2011) opinion. However, declines at the beginning of the trend period suggests that stable/fluctuating better describes the trend.
- P2129 Split from Africa population in WPE2.
- \$8717 Trolliet, B. In litt. 2012. Suggests that population maximum should be revised to 40,000 or even more likely to 20,000 individuals
- T6912 Significant long-term decline based on literature info (see CSR6).
- P2130 Split from Africa population in WPE2.
- S9115 Numbers in IWC are well below the minimum of the range, whilst past estimates have taken account of count maxima in both Eastern and Southern Africa, whereas this is a transequatorial migrant.
- S8617 Minimum raised on basis of records suggesting >500 in far west, >500 in Chad basin, >500 in Central Africa forest block and >500 elsewhere
- S8618 Generally only local in Eastern Africa, rare in South Africa, with the only high records from floodplain systems in Botswana and Zambia.
- S9147 57-59 pairs in the EU (BirdLife International 2015). Highest IWC count total in the West Mediterranean was 6,507 individuals in January 2011. Count totals have exceeded 6,000 individuals also in 2010 and 2013 (Wetlands International, 2017). There are records from several sites in Chad, including 525 recently in NE, and this year 'a dozen seen but others likely missed' in central Chad. W Africa few records, maybe 100 individuals, but could easily be underlooked eg in Mali. Based on 2013 data & Chad (Dodman, 2014).
- T6944 Long-term (1983-2015): 1.0086 (SE 0.0156) uncertain (TRIM: stable)
- \$9116 Recent IWC counts (2010-2014) from the region do not include more than 20-36 individuals from Israel. It is probably extinct in TR, its former stronghold in the region (Boyla, K., in litt, 2014). Therefore, the population estimate revised to 20-100 individuals.
- T6945 Recent information from other countries in the region except TR is not available.
- T6946 Based on data only from IR. Increase also registered in IQ, but it is uncertain whether this is the result of relocation of birds from unmonitored areas elsewhere or genuine increase.
- S9148 10,328-12,120 pairs in AT, BE, CH, CZ, DE, DK, ES, FR, HR, HU, IT, LV, NL. PL, PT, SI, SK, 43,700-64,500 wintering individuals (BirdLife International 2015), but this may include some "double reporting" especially between CH and DE. The IWC count totals were around 36,000-39,000 individuals between 2011-2015 with large amount of missing counts from ES (Wetlands International 2017).
- T6947 Increasing trend is also confirmed by breeding data (BirdLife International 2015)
- S9117 5,404-10,696 pairs in CY, GE, GR, MK, RU (25%), ME, UA and TR (BirdLife International, 2015). This yields an estimate of 16,000-32,000 individuals. The IWC count totals were around 12,000-97,000 individuals between 2011-2015 with an average of 44,000. The new estimate takes account of significant proportion of missing counts and the latest maximum count of 97,463 individuals
- T6948 1992-2015: 1.1012 (SE 0.0313), but indication of decline between the end of the 1960s and 1980s (Wetlands International 2017). Short-term trends in breeding numbers are unknown in most countries. Long-term trend is reported as negative from TR, RO and UA (BirdLife International 2015), but it is difficult to explain in the light of the much better documented increases in wintering numbers.
- \$8545 The highest IWC annual count total was 301,674 individuals in 2006, which represents the highest ever IWC count for this population.
- T7225 Both the short- and the long-term trends are uncertain but with strong negative tendency.
- T6949 Possibly in significant long-term decline.
- S9149 The total of the national wintering population estimates in IE, UK, NO, SE, FI, FR (40%), LU, BE, NL, DK, DE, PL and EE was 229,088-273,541 individuals (BirdLife International 2015). i.e. this agrees well with the estimate derived from the site level 5-year-means of the IWC counts. However, the population has suffered a steep decline. The IWC count totals were around 127,000-160,000 individuals between 2011-2015 (Wetlands International 2017) and the sum of the site-level five-year means was 200,927 individuals. Therefore, the population is revised to 200,000 individuals.
- T6950 The long-term trend is a statistically significant steep decline. The short-term trend is statistically uncertain, but with a strong negative tendency (Wetlands International 2017). Shortterm trend in national breeding populations is negative in FI, EE, LV, LT, PL, DE, DK, SK and HU. The long-term trend is also negative in even more countries (BirdLife International 2015).
- S8547 The previous population estimate of 800,000 individuals was established based on a a review of IWC data up to 2005 (Wetlands International, 2005) in CSR4. However, the IWC count totals have further decreased since then. The average annual count total was 239,025 individuals during the period of 2006-2010 and the total of the site-level 5-year-means was 379,385 individuals during the period of 2008-2012. Scott & Rose (1996) have estimated 600,000 birds for the Black Sea - East Mediterranean based on a peak count of 277,187 in Jan. 1993. Since then the max. count total was 442,662 in Jan. 1999. However, following that counts have decreased substantially and the average count total for this region was only 144,267 individuals. However, the 5-year mean was 285,696 individuals and with accounting for unsurveyed areas such as MD and EG, the population in this region is estimated to be in the range of 300,000-350,000 individuals. In Central Europe, the average count total is 75,116 individuals for the same period and the 5-year mean is 76,921 individuals, indicating a consistent coverage However, this is only half of the 150,000 birds reported by Scott & Rose (1996). In the West Mediterranean, the average count total is 116,504 individuals and the 5-year mean is 140,033 with a recent peak count of 182,000 in 2008. Accounting for missing counts, the population is estimated around 200,000 individuals. Thus, the overall estimate for the population can be estimated around 570,000-630,000 individuals.
- \$8548 Perennou et al. (1994) estimated the population size at 350,000 individuals. Maximum counts were 409,182 and 469,312 individuals in 2003 and 2004, when a major survey took place in Central Asia and the Caspian region (Solokha, 2006). The average count total was 88,727 individuals during the period of 2008-2012. Sum of the 5-year means was 193,118 individuals during the same period. However, important numbers were missed from TM (up to 52,395 individuals in 2004), UZ (up to 42,714 individuals in 2004), KZ, (up to 7,735 in 2004), TJ
- (up to 10,226 individuals in 2004), plus a couple of thousands in IQ and AM. This suggests a population size over 300,000 around 2004.

 S9150 BirdLife International (2015) estimates only 2-4 pairs in ES and PT. Dodman (2014) estimated 1900-2100 breeding pairs in NW Africa.
- S8898 16,406 27,145 pairs in Europe except ES and AZ.
- T6953 The breediing population is declining in HR, LT, LV, MD and TR, increasing in HU, IT and RS and unknown in RO which holds 64% of the entire European breeding population. The short-term trend is moderately declining (0.9911 - 0.9983). The long-term trend (1980-2012) is thought to be stable (0.9951 - 1.0015). National wintering trends in Europe are stable or increasing both in the long- and the short-term (BirdLife International 2015). The latter agrees with Trolliet (2011). However, the flyway-level trend analysis produced uncertain results (Wetlands International 2017)
- S8922 See CSR6 and Sheldon (2017).
- T7161 Wetlands International (2017) reported uncertain trend. BirdLife International (2017) has also noted: "Evidence of declines in the larger Asian populations is sparse, and sometimes
- S9151 The IWC count totals were around 333,000-464,000 individuals between 2011-2015, while the site-level 5-year mean was c. 765,000 individuals (Wetlands International 2017). The sum of national estimates of wintering birds was 957,000-1,274,000 individuals (assuming that 60% of the birds in FR belong to this population) during the period of 1994-2012 (BirdLife International 2015) including an additional 325,000 for DE which was not included into the draft used for the estimate for CSR6. Considering that some of the data is rather outdated and the double reporting" as well as the decline apparent in the IWC counts, the CSR6 estimate is retained
- T7163 IWC trend analysis shows declining tendency in the short-term. Also see notes for CSR6. Nevertheless, the population is not in significant long-term decline.

- T6955 Very steep short-term decline (0.7500, SE 0.0888), but range shift cannot be ruled out based on large increase in KZ and KG in 2014 and 2015. Long-term trend (1981-2015): 0.9722 (SE 0.0155) suggests significant long-term decline.
- \$9153 The sum of the national estimates of wintering birds between 2000-2012 was 151,960-275,126 individuals (BirdLife International 2015). The IWC count totals were around 96,000-226,000 individuals between 2011-2015 (Wetlands International 2017).
- T6956 BirdLife International (2015) reports declining trend in the breeding population both for the short-term and especially for the long-term. The long-term decline is also shown by HELCOM (2017) for wintering birds. However, wintering numbers appear to fluctuate strongly (BirdLife International 2015, Wetlands International 2017), which reflects the difficulty to monitor this species. The short-term trend is set based on breeding numbers, which are considered more reliable than the land-based counts for this predominantly marine species.
- \$8556 Scott & Rose (1996) provides justification of the current estimate. Since then the maximum count in the Black Sea region was 23,444 individuals in 2005 and 43,879 individuals in 1997 in the Caspian. There is insufficient information to revise the estimate.

 • S9141 - Updated breeding population estimates account for 352,157-523,922 pairs in Europe (BirdLife International 2015), but it does not include birds from West Siberia, which might be in
- the range of 100,000 individuals. This agrees well with the 1,000,000-1,500,000 estimates by Zwarts et al. (2009). An allowance of 100,000-200,000 individuals was made for birds in Burkhina Faso, Benin, E Senegal, W Mali, Central African Republic not covered by earlier aerial surveys of the great lakes in the Sahel.

 • T6939 - Long-term (1971-2015): strongly fluctuating with an overall stable trend.
- S8539 Peak counts from East Africa: 24,941 individuals from SD in 2010 and 10,124 in 2012 (Wetlands International, 2014). However, there are still big gaps regarding Sudd and southern N Sudan and likely elsewhere. IAsh & Atkins (2009) describe as 'very common' in Ethiopia.
- T6940 Representativity of the short-term trend is questionable. The long-term trend (1998-2014): fluctuating with a declining tendency. The short-term trend is also steep decline.
- S9118 Maximum of 1,000 applied for WPE5; minimum here increased from 1 to 100 (e.g. 45 in northern Nigeria in 2012).
- T7171 Past declining trend is quite well established (Dodman 2014), but current trend is indeed unknown. Nevertheless, it is classified being in significant long-term decline on the assumption that past trend has not changed.
- P2290 Split from S/E Africa population in WPE2.
- S8687 Number may be closer to minimum than maximum.
- T6937 Also STA/FLU in the long-term.
- P2291 Split from S/E Africa population in WPE2.
- S8688 Number may be closer to minimum than maximum.
- S8897 The 2014 count total has already exceeded the maximum estimate.
- T6941 IWC data shows a recovery from 2011 following a steep decline between 2007 and 2010.
- \$8534 The current estimate of 450,000 individuals was set by Scott & Rose (1996) assuming 100,000-170,000 individuals in the Eastern Mediterranean, 280,000 in the West Mediterranean and 20,000 for West Africa. The maximum of IWC count totals has now increased to 351,804 individuals in 2006, but these figures do not consistently include the Sahelian wetlands that supported between 15,000 and 30,000 individuals between 2000 and 2007 (Trolliet et al., 2008) and exceeded 45,000 individuals at the Senegal Delta in 2008 (Triplet et al., 2010). 84,454 individuals were counted in North Africa in January 2013. Accounting for missing counts, the total of this population now is possibly between 500,000 and 600,000 individuals
- S8535 Sum of site-level 5-year-means of IWC counts is 107,478 for SW Asia, 19,131 individuals for E Africa for 2008-2012. Maximum count in the last decade was 168,217 individuals in 2003 and most recent high count was 109,012 individuals in 2013. The proposed new estimate of 200,000-400,000 takes into account of the incomplete sampling of the flyway and the decline. (Wetlands International, 2014). Abundant in Ethiopia and must be more numerous in Sudan than recent counts suggest; but no high numbers are expected in Sudd. Could be 20K each in TZ & KE (Dodman, 2014).
- T6943 In the context of longer time series the trend is rather fluctuating then being in significant long-term decline.
 S8895 The population estimate proposed in CSR6 based on IWC data agrees well with the breeding numbers (29,867 46,069 pairs, i.e. 90,000 138,000 individuals).
- S9072 45,170-78,241 pairs in AL, AT, BA, BG, BY, CH, CZ, ES, GE, GR, HR, HU, IT, MD, MK, PT, RO, RS, RU, SI, SK, TR, UA, XK (BirdLife International 2015). The minimum estimate of breeding birds is consistent with the estimate in CSR6 based on IWC counts. However, the maximum estimate depends largely on a maximum breeding population estimate of 50,000 pairs
- \$9073 The current estimate of 130,000 individuals (Perennou, at al. 1994) based on AWC counts of 50,000-93,600 with 1970 data. The count totals in 2002, 2003 and 2007 have exceeded this estimation, but mostly ranged between 36,827 (2006) and 78,114 individuals (2010). Dodman (2014) estimate that no more than a thousand birds occur in NE Africa, largely overlooked. Considering the large counts exceeding the estimate of Perennou et al. (1994), but also taking into account the observed decline and consequently lower imputed totals (which indicate an improved coverage of the suit of sites), the current size of the population is cautiously estimated to be 90,000-130,000 individuals
- T6921 Wetlands International (2017) confirms significant long-term decline.
- S8894 The total of national wintering population estimates adds up to 1.7-2 million birds (BirdLife International 2015). However, these estimates cover slightly different periods and some double counting. Recent IWC count totals are lower than in the mid-90s to mid-2000s. The IWC count totals were around 1,105,000 - 1,226,000 individuals between 2011-2015 (Wetlands International 2017). As these totals are somewhat incomplete, the earlier estimate of 1.5 million birds was retained.
- T6916 Increased in the long-term, but decreased since 2001 and suffered c. 40% decline over the last 10 years. However, the short-term trend is statistically uncertain. Fox et al. (2016) highlighted reduced reproductive success as a possible demographic cause. Poysa et al. (2017) linked the decline to the reduced extent of Equisetum habitats.
- S9145 The IWC count totals were around 245,000 369,000 individuals between 2011-2015 with significant gaps particularly in N Africa. Taking into account of missing counts and the rate of decline, the new population size is estimates is around 390,000-490,000.
- T6917 Significant long-term decline.
- S8528 Perennou et al. (1994) estimates the size of this population to be 250,000 individual based on IWC counts ranging from 111,000 to 210,000, but this estimate relies heavily on data from the 1970s as Scott and Rose (1996) pointed out. The latter authors considered it unlikely that more than 200,000 individuals are in West Asia. However, extensive surveys in 2003 and 2004 around the Caspian Sea (Solokha, 2006) produced a total count of 138,302 and 126,702 individuals. Surveys in Arabia resulted never more than 1,500 birds in the period of 1990-1996. Scott and Rose (1996) assumed that some 5,000-20,000 birds winter in Sudan and 10,000-40,000 birds in Ethiopia (Wetlands International, 2014). The 8,500 birds counted in Sudan suggests that the former might be correct. However, in Ethiopia the maximum annual count is less than 1,800 individuals despite a fairly good coverage of key sites. However, Ash & Atkinson (2009) describes the species as very common in Ethiopia and mentions of concentrations of 2500-4000 individuals. Therefore, Dodman (2014) estimates that there could be still 20,000-35,000 individuals in NE Africa. Considering also its rapid decline, it is very unlikely that the population size currently exceeds 160,000-180,000 birds.
- T6918 Significant long-term decline
- \$8619 One estimate of 100,000 in Orange & Transvaal (South Africa) is the basis of the previous estimate, which dates from 1980s. Yet no data has ever supported the previous maximum estimate of 1 million. A more conservative upper limit is given, noting that the region where 100,000 were estimated is where it is most abundant
- \$9074 1,390,900-2,243,710 pairs in BE, DE, DK, EE, FI, FO, IE, IS, LT, LU, LV, NL, NO, PL, SE, UK (BirdLife International 2015). IWC count totals varied between 1,324,000-1,581,000 individuals during 2011-2015 (Wetlands International 2017).
- \$9075 1,257,872 1,366,994 wintering individuals reported from PT, ES, FR, ES, FR (70%), CH, DE (30%), CZ, PL (50%), AT, HR, SI, IT, MT and HU (BirdLife International 2015). The estimate includes an additional 50,000-150,000 individuals for North Africa and for missing counts and the proportion of the population not included into the counts.
- \$9146 The IWC count totals were around 346,000-808,000 individuals between 2011-2015 (Wetlands International 2017). BirdLife International (2015) estimated the wintering numbers at 475.562-1.119.722 for the period 2000-2014 Russia not included where near 400.000 individuals were counted in recent years. Considering the large amount of missing count, the current
- T6929 The new trend analysis shows that the population has recovered from the earlier long-term decline reported in earlier editions of the WPE and CSR until 2011.
- \$9136 811,065 individuals were still reported from January 2004, but much lower numbers afterwards. However, it is possible that range shift would be undetected in the less intensively monitored Central Asian Republics. Therefore the earlier estimate of Perennou et al (1994) is retained.
- T6930 In the short-term the population shows a recovering tendency. In the long-term the significant long-term decline has changed to a moderate decline indicating that the population has not yet fully recovered.
- P2169 In WPE2 this population belonged to one single population (E Africa to Western Africa).
- S8684 4355 counted in January 2005 in Kenya & Tanzania
- P2170 In WPE2 this population belonged to one single population (E Africa to Western Africa).
- T7224 Clear long-term decline, but current status is uncertain
- \$9076 Re-evaluation based on counts up to 2013 and records from across region. Probably up to 2,000 in Botswana, 10,000-20,000 in Namibia, 10,000 50,000 in South Africa; very few elsewhere.
- T6926 Long-term increase.
- P2257 Split from Southern & Eastern Africa population in WPE2.
- S8686 No new data to suggest change, but estimate could no doubt be improved upon in future.
- T6935 Long-term trend is stable.
- P2258 Split from Southern & Eastern Africa population in WPE2.
- S8620 Baker (1997) estimates up to 30,000 for Tanzania, this being a key country for this population; estimates from other countries suggest this more conservative range
- . T6936 Stable/fluctuating both in the long- and the short-term.
- T7172 Significant long-term decline is assumed based Scott & Rose (1996). IWC count totals have decreased from c. 800 to c. 250 in 2004 and 2014, but the data is not sufficient for trend
- \$9078 Total of the national wintering populations reported from BE, CH, DK, FR, IE, NL and the UK is 65,884-89,559 for the period of 2000 and 2012 (BirdLife International 2015). However, this certainly represents some double counts. IWC count totals for the period of 2003-2012 ranged between 43,779 (2010) and 80,476 (2007) with a five year mean of 56,495 individuals (Wetlands International, 2014) and 54,000-70,000 individuals between 2011 and 2015 (Wetlands International 2017). Considering the lower counts in recent years, a new estimate of 65,000 individuals was adopted.
- T6932 Following a strong increase until the early 2000s, the population trend showed some rapid decline until 2010. After that, however, numbers have increased again, and the short-term

represent the population. Trolliet et al. (2008) and Zwarts et al. (2009) estimated the numbers in the Sahel around 400,000 individuals

- T6933 The population is in the declining phase of a long-term fluctuation with an overall moderately increasing tendency. The long-term trend is stable/fluctuating.
- S8921 See CSR6 and Sheldon (2017).
- T6934 Significant long-term decline. In the short-term the declining tendency continued, but this is statistically not significant.
- S8896 During 2011-2015, the average annual IWC count total ranged between 343,000 and 427,000. The sum of the national wintering population estimates for IE, UK, FR (80%), BE, NL, LU, DE, DK, ES, CH was 484,472-532,658 individuals in varying periods of five years between 2000 and 2012 (BirdLife International 2015). An additional 1,000-5,000 individuals are reported from PL during the period of 2011-2015 (Wetlands International 2017), which includes the current point estimate. Therfore, it is retained.
- \$9079 The IWC count totals were between 568,649 727,247 individuals between 2011-2015 (Wetlands International 2017), but with substantial gaps and low consistency of count coverage at many places. The imputed total at regularly counted sites was 818,000. BirdLife International (2015) reported 384,761-699,570 individuals from European countries without RU. The mean IWC count total in RU was 15,888 individuals with 56,250 counted in 2011. Based on the IWC counts, another 32,000-141,000, or most likely more, individuals are in the S & E
- T6923 Strong increase in the short-term. The long-term trend is stable.
- S9135 The estimate of Perennou et al. (1994) is mainly justified by some high counts in the 1970s. In SW Asia, counts around 800,000 were only recorded in 2003, but later only smaller numbers were counted despite some major regional efforts in 2004 and 2005 as well (Solokha, 2006). The maximum count total was 311,245 in 2012 and the total of the site-level time totals also do not exceed 360,000 individuals (Wetlands International, 2014). In northeast Africa, the maximum count was 1,920 inidividuals in Ethiopia in 2012 and 2,794 in Sudan in the same year despite increased efforts. Dodman (2014) suggests that there could be less than 20,000 individuals in NE Africa. It is unlikely that the size of this population still exceeds 1,000,000, but it is probably still more than 500,000
- T6924 Stable short-term trend, but significant long-term decline.
- S8824 124,848-198,925 pairs in Europe without AZ and AM (BirdLife International 2015). Further, less than 5,000 individuals in North Africa (Dodman, 2014).
- T6780 The short-term population growth rate of wintering birds is 0.9738 (SE 0.0313) indicating some decline (Wetlands International 2017), but breeding numbers show a stable trend stable (EBCC 2016) or uncertain (BirdLife International 2015). In the long-term, the population has strongly increased based on mid-winter counts (1988-2015; Wetland International 2017) or remained stable based on common bird monitoring (EBCC 2016).
- S8825 12,420-18,415 breeding pairs in FI, DE, DK, SE, PL, RO, LV, EE, LT, BG, HU, NL, SK, SI, FR and CZ (BirdLife International 2015).
- T6781 Decreasing only in EE, increasing in the large populations of DK, Fl and SE, stable or fluctuating in DE, FR, LT, NL, unknown in LV and PL (BirdLife International 2015)
- \$8826 15,528-29,478 pairs in AM, BY, GE, RS, RU, TR and UA (BirdLife International 2015).
- T6782 The large RU population is slightly increasing, the small populations in BG, RO, RS and TR are decreasing, stable or fluctuating in other countries. In the long-term it appears to be stable in most countries except the small populations in HU, RO and TR.
- S8455 No more than 1,023 (2004) counted during IWC counts (Solokha, 2006).
- T7166 O'Donnel and Fjeldsa (1997) suggest that it has increased in the Caspian. Previous assessment was STA based on information from BirdLife International (2002). However, count totals are declining, but coverage is sparse and too irregular to judge the trends.
- S8827 171,000-254,603 pairs in AT, BE, CH, CZ, DK, EE, ES, FR, IE, IT, LT, LU, LV, NL, NO, PL, PT, SE and UK (BirdLife International 2015).
- T6783 Following a long-term increase both in the breeding and wintering numbers, the population appears to be stable or slowly declining in the short-term (Wetlands International 2017, BirdLife International 2015, EBCC et al. 2016).
- S8828 156,645-238,670 pairs in AL, AM, BA, BG, BY, GE, GR, HR, HU, MD, ME, MK, RO, RS, RU, SI, SK, TR, UA and XK (BirdLife International 2015).
- T6784 The breeding population appears to be stable in all range states except MD in the short-term. In the long-term, trends are mostly unknow. Decline was reported from TR, increase from BY (BirdLife International 2015). The IWC trend analysis indicates continued increase both in the long- and the short-term although the latter is statistically not significant (Wetlands
- S8900 See CSR6 for wintering numbers and Sheldon (2017) for breeding numbers.
- P1432 These populations were treated as a single larger population WPE1. (WPE2)
- P1433 These populations were treated as a single larger population WPE1. (WPE2)
- S9119 Several coordinated counts of over 1,000, but counts have never reached 2,000
- T6787 Continued increase since the mid-1990s (Wetlands International 2017)
- S8829 1,530-1,680 pairs in IS, NO, SE and UK (BirdLife International 2015).
- T6788 The NO population is estimated to have declined by 15-50% and the UK by 47% in the short-term. This is not compensated by the 10-29% increase in the IS and 0-100% increase in the SE population (BirdLife International). However, the IWC trend analysis indicates a more stable/fluctuating or even slightly increasing trend (Wetlands International 2017).
- \$8830 4,910-7,545 pairs in EE, FI, LT, LV, RU, SE and UA (BirdLife International 2015).
- T6789 The breeding population is decreasing in the large population of FI, increasing in LT and SE, stable in DE and EE, unknown in LV and RU. The overall short-term trend is negative (BirdLife International 2015). The IWC trend analysis also confirms the short-term decline (Wetlands International 2017). The long-term trend of the breeding population is considered to be strongly decreasing based on trends in breeding numbers (BirdLife International 2015) while the IWC data suggest a stable long-term trend (Wetlands International 2017).
- S8901 See CSR6 and Sheldon (2017)
- S8831 46,222-77,282 pairs in Europe excluding AZ (BirdLife International 2015). C. 50-300 pairs in NW Africa (Dodman 2014).
- T6791 The IWC trend analysis suggests a statistically not significant but substantial short-term decline 2006-2015: 0.9630, S.E. 0.0357 (Wetlands International 2017). The short-term trend of the breeding population is unknown (BirdLife International 2015). The long-term trend is stable based on both the breeding and the non-breeding data.
- S8902 See CSR6 and Sheldon (2017).
- T6792 The population is in significant long-term decline based on mid-winter counts (Wetlands International 2017).
- S8599 Based on July counts, especially from Walvis Bay, Namibia
- T6793 Overall stable since 1980 with large year-to-year fluctuations. Dodman (2014) assumes that the trend is linked to seasonal rains. Strong increase in the short term (Wetlands International 2017).
- P1869 Recognised as a separate species from ruber following BirdLife. (WPE4)
- \$8613 >100000 in Jan counts 2005; IWC: >75000 in 2005, ca. 50000 in 2006. Some sites always missing from surveys.
- T6858 IWC trend analyses based on data from regularly counted sites in KE and ET indicate statistically significant steep decline particularly from the second half of the 2000s. This is also consistent with the change in national count totals (Wetlands International 2017). Dodman (2014) has given a stable trend with reference to counts from a period before (!) the decline has accelerated. In the absence of any strong evidence to the contrary, the findings of the trend analysis are retained based on the precautionary principle while recognising the uncertainties involved when the range of a highly nomadic and congregatory species has a low count coverage.

 • P1870 - Recognised as a separate species from ruber following BirdLife. (WPE4)
- S8614 Regular counts of >90,000; up to ca. 150,000. ca. 17000 pairs at Sua Pan in 2008
- T6859 IWC data confirms long-term increase since the mid-1990s with large fluctuations in recent years following earlier decline.
- P1871 Recognised as a separate species from ruber following BirdLife. (WPE4)
- T6860 Although the IWC trend analysis shows a steep decline since 1980 (Wetlands International 2017) this should be treated with caution because it may just reflect chance events in the dsitribution of birds. van Roomen et al. (2015) also highlighted large fluctuations in January IWC counts, but the trend from 2001 agrees well with the increase in breding numbers reported by Dodman (2014).
- P1872 Recognised as a separate species from ruber following BirdLife. (WPE4)
- S8864 A total of 37,829 pairs bred in ES, FR, IT in 2014 (Diawara et al. 2014). Over 11,000 pairs bred also in North Africa (Dodman, 2014).
- T6861 Both the long- and the short-term trends are positive in Europe (BirdLife International 2015). New colonies are reported from NW Africa (del Hoyo 2017). The IWC trend analysis indicates strong increase both in the long- and the short-term (Wetlands International 2017).
- P1873 Split from East Mediterranean, South-west & South Asia in WPE4. Recognised as a separate species from ruber following BirdLife. (WPE4)
- S8820 Maximum IWC count results from AL, CY, EG, GR, IL, JO, LY and TR (Wetlands International, 2017) is 148,000. Further 10,000-20,000 wintering in Egypt (Dodman, 2014). T6775 - IWC trend analysis shows strong increase both in the long- and the short-term (Wetlands International, 2017)
- P1874 Split from East Mediterranean, South-west & South Asia in WPE4. Recognised as a separate species from ruber following BirdLife. (WPE4)
- T6862 The long-term trend is stable with large fluctuations. Limited data from other countries than IR.
- P1882 Often placed in genus Phoeniconaias.
- S8865 van Roomen et al. (2015) reported an average of 23,000 birds from regularly counted sites. 26,884 indivduals were counted in 2015 (Wetlands International 2017). The new estimate makes allowance for both double counting and missing counts
- T6863 Trend based on mid-winter counts show increase (van Roomen et al. 2015, Wetlands International 2017), but Dodman (2014) cautions that coverage is insufficient, although count totals also show steady increase.
- S8674 No new data that suggests need to change
- T6864 Significant long-term decline based on IWC data, but trend is based only on data from ET and KE.
- S8615 2008: breeding at 3 sites ca. 170,000 birds (Sua, Etosha, Kamfers); IWC data up to 130,000 (2007).
- T6865 Both the long- and the short-term trends are statistically uncertain, but the long-term stable and short-term increasing tendency agrees with earlier assessments.
- T6241 Population on Ascension Island seems to be stable and data is insufficient to estimate trend on St. Helena.
 S8914 See CSR6 and Sheldon (2017).
- T6242 No new population trend estimate is available for this sub-species, however populations are under threat in the Persian Gulf.
- T6244 New data inadequate to revise trend. Current trend supported by population estimates in the Seychelles considered stable. On Mauritius some populations are increasing and others

negative in the remaining countries, the long-term one is stable. Hence, no evidence supports that the population is in significant long-term decline.

- P249 Sometimes placed in genus Crex
- S8625 8.000 estimated in South Africa (Taylor 1997).
- T6613 Long-term trend is probably stable according to Taylor and Perlo (1998)
- S8998 1,294,132-2,120,311 calling males in Europe (BirdLife International 2015). A further 515,000-1,240,000 calling males are estimated for Asiatic Russia (Schäffer and Mammen 1999).
- . T7080 The European population is stable both in the short- and the long-term.
- S9001 161,334-250,610 pairs
- T7083 The trend is unknown in 15 countries, stable or fluctuating in 17, declining in 3 and increasing in 1. BirdLife International (2015) has assessed the European trend as unknown.
- S8999 54,960 82,945 pairs in Europe (BirdLife International). An additional 20,000 pairs are assumed for the W Asian part of the range.
- T7081 Majority of national trend are unknown (17), fluctuating (4) or increasing (3 including RU). Reported to decline only from SK and MD.
- S9000 168 558 pairs without RU and TR, which belong to the subspecies 'pusilla' and were incorrectly included into the earlier estimates
- T7082 The trend is unknown in 14 countries, increasing in 2 (including RU), stable or fluctuating in 4, declining only in ME.
- T6750 No trend information is available from the last decade. However, significant long-term decline is assigned based on Taylor and Perlo (1998).
- T7085 Possibly in significant long-term decline. The population might have declined by c. 14% in 16 years.
- S9002 908,962-1,436,708 pairs in Europe (BirdLife International 2015). Common resident in NW Africa, but no estimate is available (Dodman, 2014).
- T7084 Trend based on IWC counts indicate a short-term decline (Wetlands International 2017). This agrees well with trend based on common breeding bird monitoring (EBCC et al. 2016). BirdLife International (2015) classified the short-term trend as stable. All of these sources agree on a stable long-term trend.
- S8924 Erroneous entry in CSR6. In the absence of any information, old estimate is maintained.
- T7175 Declining both in the short- and the long-term, but the long-term decline does not significantly exceed the threshold for significant long-term decline
- T7226 Dowsett & Dowsett-Lemaire (2006) indicates that extensive hunting in Malawi may have impacts.
- S9081 Five year mean of count totals is c. 2,500 individuals. The maximum count is 5,126 individuals.
- T7086 Earlier assessments were based on data from ES which represents only a small fraction of the population. The new assessment is based on IWC counts from boh ES and MA. Strong increase in the long-term.
- S8626 IWC data suggest at least 250,000.
- T7087 Moderate decline in the short-term. Stable trend in the long-term, but it is based data mostly from ZA.
 \$9003 388,993-662,601 pairs in AT, BE, CH, CZ, DE, DK, EE, FI, FR, IE, LI, LT, LU, LV, NL, NO, PL, SE & UK (BirdLife International 2015). The IWC count totals were between 775,000 and 945,000 during the period of 2011 and 2015 (Wetlands International 2017).
- T7164 Stable both in the short- and the long-term (Wetlands International 2017). However, BirdLife International (2015) suggests decline in the breeding numbers both in the short- and the long-term
- S9004 545,938-862,820 pairs in AL, AM, BA, BG, BY, CY, ES, GE, GR, HR, HU, IT, MD, ME, MK, PT, PTMA, RO, RS, RU, SI, SK, TR, UA & XK. This agrees well with the estimate based on IWC data
- T7088 IWC trend analysis shows stable trend both in the long- and the short-term with a negative tendency in the short one (Wetlands International 2017). BirdLife International (2015) reported decline based on breeding numbers, but the national trend was uncertain in 9 of the 25 countries and dominated by a 40-60% decline reported from RU.
- \$8293 The average IWC count total was 516,191 individuals during the period of 2008-2012. The sum of the site-level 5-year means was 1.421,369 individuals during the same period. The peak count was 1,538,658 in 2007. Considering that important parts of the region were not counted, the estimate of 2,000,000 birds for this population (Perennou et al. 1994) appears to be
- T7089 Stable long-term trend. This confounds that the earlier increasing population trend has turned into a steep decline from 2006.
- T6611 Declined population with fragmenting range and contracting area of occupancy. Apparently increasing in KwaZulu-Natal, 2001-2010 (Smith et al. 2010).
 T6612 Significant long-term population decline with fragmenting range and rapidly contracting area of occupancy
- S8691 2,000 recorded at Zakouma (Chad) in 2014, indicating possibility of reasonable numbers still in areas not often surveyed.
- T6754 The population has gone through significant long-term decline and the continuation of population decline is assumed by several authors (Trolliet in litt. 2011, Dodman 2014, Morrison, in litt. 2014).
- T6693 Short-term trend is unknown, but continuation of significant long-term decline is retained based on past decline.
- P8 In previous WPE editions, placed in the genus Grus.
- S8597 Only 1 individual was located in Iran in 2011/2012.
- T6681 Number of observed birds declined from 6 to 1 at its wintering ground in IR.
- P40 In previous WPE editions, placed in genus Grus. Split from S Africa & Ethiopia population in WPE2.
- T7022 The population is though to be stable now (K. Morrison, in litt. 2017). However, significant long-term decline is assumed based on past decline (Beilfuss et al. 2007) and habitat loss (Dodman 2014).
- P35 Split from Africa population in WPE2. In previous WPE editions, placed in the genus Grus.
- P29 In previous WPE editions placed in the genus Grus. Split from Kalmykia/North-east Africa population in WPE2. T7025 - Habitat is decreasing.
- P30 In previous WPE editions placed in the genus Grus. Split from Kalmykia/North-east Africa population in WPE2.
- T6984 Information from the Turkish Breeding Bird Atlas project.
- P31 In previous WPE editions placed in the genus Grus. Split from Kalmykia/North-east Africa population in WPE2.
- S8954 9,500-13,000 pairs.
- T7026 Long-term trend is fluctuaing.
- P44 Morphologically distinct form, proposed as G.g. archibaldi, described in Shirak province, Armenia, in 2008. (Ilyashenko 2008)
- \$8952 Birdlife International (2015) estimated the size of the population breeding in RU, BY and UA at 26,500-42,300 pairs, i.e. 80,000-127,000 individuals, which agrees with their previous estimate. Considering that Nowald et al (2010) counted about 60,000 individuals in Ethiopia and at the same time around 35,000 individuals also wintered in Israel in 2010 (Shanni et al., 2012), the breeding numbers are most likely correct.
- T6279 BirdLife International (2004) estimated the trend of the Russian breeding population 0-19% increase during the period of 1990-2000. Shanni (2012) indicated an increase from a few hundred birds to 35,000 in the Hula Valley in Israel and suggests that this only partly due to range shift.
- P45 "lilfordi" not widely recognised.
- S8953 36-42 pairs breed in AM, GE, TR. Ilyasenko (2016) provides an estimate of 230-265 individuals from TR and GE.
- T6280 90-90% decline reported from TR. No updated info from GE yet (BirdLife International et al., in prep.). This population qualifies for significant long-term decline.
- P46 Information provided by George Archibald, October 2001.
- S8821 62,081-143,031 pairs in Europe (BirdLife International 2015). Further 20,000-50,000 pairs were estimated to be breeding in West Siberia following WPE4 (Wetlands International
- T6776 BirdLife International (2015) assessed the short-term population to be unknown for Europe, stable for the European Union. No information is available from West Siberia. The longterm population trend is also unknown.
- S9049 The breeding range in RU overlaps with the one of the population wintering in NW Europe. 30,000-50,000 pairs in European RU (BIrdLife International, 2015) and similar numbers are assumed to breed in W Siberia (Delany and Scott, 2006). Only 2 individuals recorded during the comprehensive surveys around the Caspian Sea (Solokha, 2006).
- T7165 Short-term trend is unknown in RU, but long-term (1980-2012) trend is reported as stable.
- S8822 88,790-155,750 breeding pairs in Europe (BirdLife International 2015). Wetlands International (2006) assumed further 35,000-70,000 pairs in West Siberia
- T6777 BirdLife International (2015) has assessed the short-term trend of the European population to be decreasing and the European Union one to be stable. No information is available from the Siberian part of the range.
- S9050 Usually less than 30 individuals are observed annually during the IWC. However, Solokha (2006) reports 337 individuals from the Caspian region of which 328 from Turkmenistan. 129 and 116 individuals were also reported in January 1999 and 2000.
- S8823 Sum of national wintering population estimates.
- T6778 According to (BirdLife International 2015), wintering numbers declined in IE, UK and ES (i.e. the bulk of the European wintering population) and were stable in CH, SE and IS, fluctuated in FR in the short-term, but strong increase is reported from both SE and UK in the long-term. The long-term trend is unknown in other countries. The trend based on the IWC shows large increase both in the short- and long-term (Wetlands International 2017). The IWC trend is driven largely by data from Germany (contributing more than 50% to the sample totals), which country is even not reported wintering numbers to the European Red List.
- \$7055 The European wintering population is estimated at 1,000 individuals (BirdLife International 2015). The whole Russian breeding population is estimated at 8,000 individuals (US Fish and Wildlife Service 2009). It is unknown what proportion of these birds actually winter on European waters
- S8202 5500 pairs in Namibia, 18,640 pairs in South Africa
- T6853 Result of IWC trend analysis (Wetlands International 2017) agrees with the circumstantial evidence presented by Dodman (2014) and BirdLife International (2017).
- S8666 Max in WPE5 was erroneously low of reference; increased again when reviewing newer literature & recent IWC counts for West Africa.
- S8667 No recent data to suggest change.
- S8668 Review of more recent references does not merit change in estimate.
- T7176 The species has suffered very large decline in two-third of the species' grid cells between SABAP1 and 2. No trend information is available from other range states
- S8858 The total of national population estimates is 1,197-1,277 pairs assuming that 30% of Czech, 50% of German and 10% Polish birds follow the western migration route.
 S8859 8,507 12,421 pairs in CZ (70%), PL (90%), DE (50%), AT, BG, EE, HU, LT, LV, RO, SE, SI, SK, AL, AM, AZ, BY, BA, HR, GR, MK, MD, RS, ME, TR, UA & RU (BirdLife International

stable/fluctuating tendency in this countries although based on rather limited data. It is unclear whether the decline in ZA is related to range shift or also represents a decline at population

- P2012 Ciconia episcopus and C. microscelis (del Hovo and Collar 2014) were previously lumped as C. episcopus (see BirdLife International (2016) Species factsheet; Ciconia microscelis.)
- S9120 Based on regional estimates across Africa
- T6851 No widespread threats noted; only potential increase observed in South Africa, where population very small (Dodman 2014, Smith et al. 2017). Results of IWC trend analysis are uncertain for both the long- and short-term but indicate overall positive tendency (Wetlands International 2017).
- T6651 Fluctuating trend of a small population, but overall seems to be stable.
- T7177 Overall large increase (4% and 3%) during 2000-2012 and 1980-2012 respectively.
- \$8861 171,345 186,954 pairs in AT, BA, BG, BY, CH, CZ, DE, GR, HR, HU, LT, LV, MD, ME, MK, PL, RO, RS, RU, SI, SK, TR, UA & XK.
- T6852 Increasing both in the short- and the long-term.
- T6511 No recent information is available.
- \$9082 Estimate quality is reduced to 'Best guess' because the maximum estimate is more than twice larger than the minimum.
 T6857 The short-term trend is highly uncertain, therefore, the long-term trend is presented here.
- S9133 The total of national breeding population estimates from the EU Birds Directive Art. 12 reporting process is 4,664-5,485 pairs. Based on data from 2012, Overdijk et al. 2013 gives the figure of 4,729-6,301 pairs in 102 colonies. The latter was adopted here considering that it is more recent and provided by a specialist network. Van Roomen et al. (2015) accounted for 18,310 individuals based on winter counts in Europe and West Africa after deducting numbers for P. I. balsaci. Considering that immature birds remain in Africa until they reach breeding age and the on-going population growth, it is likely that the population size is closer to the upper limit than to the lower one.
- T7162 Based on the national trend data for breeding birds, the population has increased by 49-79% over the last decade and by 167-173% over the last 3 decades (BirdLife International 2015). van Roomen et al. (2015) have also shown large increase both in the long- and the short-term based on mid-winter counts.

 • S8863 - 3,689 - 5,630 pairs in AL, AT, BA, BG, CZ, GR, HR, HU, IT, MD, ME, MK, RO, RS, RU (assuming that 50% belongs to this population), SK, TR & UA.
- T7178 Short-term decline, which is driven by decreasing numbers in RU and TR. Increased in the long-term.
- \$8584 750 pairs multiplied by 3.
- T6577 Steady decrease from 1600 pairs in 1996 towards 750 pairs in 2012. Based on this rapid decline, the population is considered to be in significant long-term decline
- S9134 Triplet et al (2008) accounted for 894 1357 pairs. However, Dodman (2014) considered that the estimate for Eritrea is too low and that broader range is needed to accommodate unknown/outdated numbers from e.g. Sudan and Somalia.
- T6504 Overview in Shobrak et al. (2003). Decline reported from EG and DJ to Triplet et al. (2008).
- P1963 Often included in nominate.
- S8234 Based on questionnaire survey in 2007.
- T7232 Wetlands International 2012, Trend 1995-2007; -0.6% p.a. ? Uncertain.
- T6502 Khaleghizadeh (2011) reports increasing frequency of observations in Iran.
- S9083 Post-breeding numbers.
- T7179 An unquantified decline is indirectly estimated to have occurred over the last three generations. The Moroccan population has been stable since 1980 (BirdLife International 2017) although they report increasing numbers during the last decade
- S9084 Reportedly no birds returned in 2015.
- T7180 Last breeding observed in Syria in 2012 and possibly extinct now as a breeding species. However, one individual has been reported in Ethiopia which likely represents an individual that has migrated from Syria (Bowden pers. com cited by Westrip 2017).
- S8611 Recent analysis that discounts the extremely high estimate of Range Ecology Survey (1983) from the Sudd.
- T6855 The short-term trend is rather uncertain, therefore the long-term IWC trend is used. This suggest a stable long-term trend (Wetlands International 2017). Underhill et al. (2016) found that the species has increased in both range and abundance over the Western Cape but has mixed fortunes elsewhere in ZA.
- T6856 BirdLife International (2015) assessed the short-term trend of the European population as increasing. However, the short-term trend is unknown or fluctuating in 8 of 14 breeding range states. Long-term trend is fluctuating in 7, but the overall long-term trend is stable in the remaining range.
- P1855 In WPE2 this population belonged to one single population (Europe (breeding)).
- S8854 2,375 3,013 pairs in BE, DE, DK, ES, FR, NL, PT, SE & UK (BirdLife International 2015). Less than 20 pairs in NW Africa (Dodman, 2014).
- T6842 Increased both in the long- and the short-term.
- P1856 In WPE2 this population belonged to one single population (Europe (breeding)).
- S8855 30,754 54,355 pairs in AL, AT, BA, BG, BY, CZ, EE, FI, GE, GR, HR, HU, IT, LT, LV, MD, ME, MK, PL, RO, RS, RU (assuming 70%), SI, SK, TR & UA (BirdLife International 2015).
- T6843 The population has increased in the short-term, but the short-term trend is unknown in 7 of 26 breeding range states. The long-term trend is possibly stable, but unknown in 10 of 26 range states.
- S9121 Fragmented population, only low numbers assumed from any site.
- T7181 Dodman (2014) assumed decline based on fragmented population and habitat loss in many areas. ADU (2017) data confirms that that the species was absent in 16 quarter degree grid cells in SABAP2 where it was present during SABAP1, declined in one and occupied only 5 new ones.
- P1814 In WPE2 this population belonged to one single population (Europe/Northern Africa (bre)).
- \$8856 6,227-8253 pairs in BE, DE, ES, ESIC, FR, IT, LU, NL and PT (BirdLife International 2015). 100-200 pairs in NW Africa (Dodman, 2014).
- T6844 Stable in the short-term but declined in the long-term.
- P1815 In WPE2 this population belonged to one single population (Europe/Northern Africa (bre)).
- S8857 55,156 98,469 pairs in AL, AT, BA, BE, BG, BY, CH, CY, CZ, DE, ES, ESIC, FR, GE, GR, HR, HU, IT, LT, LU, LV, MD, ME, MK, NL, PL, PT, RO, RS, RU, SI, SK, TR, UA & XK (BirdLife International 2015). Further 1000 pairs in Egypt (Dodman, 2014).
- T6845 Stable both in the long- and the short-term.
- P1762 In WPE2 this population belonged to one single population (Europe/NW Africa (breeding)).
- \$8852 14,836 15,596 pairs in BE, DE, ES, ESIC, FR, IT, NL and PT (BirdLife International 2015), Dodman (2014) estimated that 500-1500 pairs may breed in NW Africa.
- T7231 The European part of the population has declined by 50-53% over the last decade.
- P1769 In WPE2 this population belonged to one single population (Europe/NW Africa (breeding)).
- S8853 44,700 69,610 pairs in AL, AT, AZ, BA, BG, BY, GE, GR, HR, HU, MD, ME, MK, PL, RO, RS, RU, SI, SK, TR, UA& XK (BirdLife International 2015). In addition, less than 1000 birds in Egypt (Dodman, 2014).
- T6840 Stable both in the short- and the long-term.
- S9122 Widespread, with breeding colonies across sub-Saharan Africa
- T6841 Dodman (2014) considered it to be at least stable. IWC trend analysis shows strong increase both in the long- and short-term, but this is driven by data from SN (Wetlands
- S8848 8,495-10,703 pairs in ES, FR, IT & PT (BirdLife International 2015). C. 100 pairs in N. Africa (Dodman, 2014).
- T6825 Increased both in the short- and the long-term.
- P1703 In WPE2 this population belonged to one single population (S&SW Asia/Black Sea (bre)).
- S8849 9,219-16,569 pairs in AL, BA, BG, CY, GE, GR, HR, HU, MD, ME, MK, RO, RS, RU, SK, TR & UA (BirdLife International 2015). In addition, over 600 breeding pairs in Egypt (Dodman, 2014).
- T6826 Declining both in the long- and the short-term.
- P1704 In WPE2 this population belonged to one single population (S&SW Asia/Black Sea (bre)).
- P1705 Sometimes ascribed to ralloides
- T6828 Significant long-term decline. BirdLife International (2017) suspects that the decline continues. However, IWC count data suggest modest increase after 2000 (Wetlands International 2017).
- P1685 Often placed in genus Ardea.
- T6820 The short-term trend has a strong negative tendency. The long-term trend is also significant long-term decline (Wetlands International 2017). It has declined in three times more quarter degree grid cells than increased in ZA between the SABAP 1 and 2 (ADU 2017).
- P1694 Often placed in genus Ardea.
- S8651 Population probably numbers 'several million' (Dodman, 2014).
- T6821 IWC trend analysis produced uncertain results.
- P1695 In WPE2 this population belonged to one single population (SW Europe/NW Africa). Often placed in genus Ardea. T6822 - Stable long-term trend.
- P1696 In WPE2 this population belonged to one single population (SW Europe/NW Africa). Often placed in genus Ardea.
- S8847 71,770 84,193 pairs.
- T6823 Both the breeding (BirdLife International 2015) and the IWC data (Wetlands International 2017) indicate long-term increase that turned into a decline in the short-term.
- P1697 Often placed in genus Ardea.
- T6824 Although the trend analysis suggest steep decline, Hatzofe (pers. com) indicated that the species has exploded in IL.
- S9124 approx 50,000 in Southern Africa, up to 100,000 in Eastern Africa, up to 100,000 in Western Africa, and up to 50,000 in Central Africa
- S8841 Total number of breeding pairs is 115,754-237,071 pairs, i.e. 347,000-711,000 individuals BirdLife International 2015). Less than 300 birds breed in North Africa (Dodman, 2014).

and stable long-term one

- P1635 In WPE2 this population belonged to one single population (E B Sea & W/SW Asia (bre)).
- S8907 See CSR6 and Sheldon (2017).
- T6811 Statistically uncertain short-term trend with a negative tendency. The long-term trend is stable.
- T6817 According to the IWC trend analysis data, the population is possibly in significant long-term decline although only partial information is available (Wetlands International 2017).
- S8845 10,802-12,400 pairs in CH, NL, DE, IT, FR, ES and PT (BirdLife International 2015). Less than 300 in North Africa (Dodman, 2014)
- T6818 Declining in the short-term. Long-term trend appears to be stable (BirdLife International 2015).
- \$8846 20,411-32,945 pairs (BirdLife International 2015). This estimate is without the estimate for SW Asian part of the population, which was split from
- T6819 Declining both in the short- and the long-term. Unknown breeding trends are reported from 7 of the 20 breeding range states (BirdLife International 2015).
- P1665 In WPE2 this population belonged to one single population (E Europe/SW Asia (breeding)).
- S8489 WI/IUCN Heron SG (2005)
- P1672 Often assigned to genus Casmerodius, occasionally Egretta.
- S8843 20,248-32,928 pairs in Europe (BirdLife International 2015). Possibly, some birds in the Volga delta belong to the Western Asia/South-west Asia population.
- T6812 In the short-term, increased based on breeding numbers (BirdLife International 2015), but stabilized based on wintering numbers (Wetlands International 2017). In the long-term, increase based on both source.
- S8908 See CSR7 and Sheldon (2017).
- T6813 Stable both in the short- and the long-term (Wetlands International 2017). The trend graph shows increase up to the late 1990s, followed by a rapid decline in the early 2000s and stabilisation in the last decade.
- T6814 Stable both in the short- and the long-term.
- P1680 Ardea intermedia, A. brachyrhyncha and A. plumifera (del Hoyo and Collar 2014) were previously placed in the genus Mesophoyx and lumped as M. intermedia (see BirdLife International (2016) Species factsheet: Ardea brachyrhyncha.)
- S8658 No update to estimate in AEWA SSAP (Tyler 2013)
- T6830 The population is suspected to be in decline owing to the effects of habitat conversion and degradation, and human disturbance. The likely rate of decline, however, has not been estimated (BirdLife International, 2017). Recent IWC trend analysis provides some week support to this assumption (Wetlands International 2017). Significant long-term decline maintained.
- T6832 Trend analyses based on IWC July data suggest a significant increase, however data are rather limited to a few key countries
- P1601 Population was omitted from WPE2.
- S8850 34,668-34,472 pairs in BE, ES, ESIC, FR, IE, IT, NL, PT & UK (BirdLife International 2015). 1500-3500 resident birds can be also added for NW Africa (Dodman, 2014).
- T6833 Declines in the short-term but increased in the long one.
 \$8851 19,598-29,059 pairs in AL, AT, BA, BG, CY, CZ, GE, GR, HR, HU, MD, ME, MK, PL, RO, RS, RU, SK, TR, UA & XK (BirdLife International 2015) allocating 40% of the Russian population to this one. According to Dodman (2014), further 1000-2000 resident birds can be added for Egypt.
- T6834 Stable in the short-term and stable/fluctuating in the long one.
- T6835 Stable/fluctuating in the long-term. This overall trend confounds large long-term fluctuation.
- P1609 This form and schistacea sometimes treated as separate species, Western Reef Heron. Sometimes assigned to Egretta garzetta.
- S9127 Review of more recent data, including 2013 and 2014 counts
- T6836 Van Roomen et al. (2015) found increasing trend based on the IWC data. Wetlands International (2017) found that the long-term trend is stable/fluctuating, the short-term is uncertain. Wetlands International's assessment agrees well with Dodman (2014).
- P1610 Sometimes assigned to Egretta garzetta schistacea.
- S8912 See CSR6 and Sheldon (2017).
- T6837 Dodman (2014) assumed that the population is stable in the absence of human impacts along the Red Sea coast. Reviewing of available IWC data and the formal trend analysis suggest that a steep decline might have taken place between 1990 and 2015 (Wetlands International 2017). This is probably driven by destruction of coastal wetlands and mangroves particularly along the northern coast of the Red Sea (Nagy et al. 2014).
- P1611 Sometimes assigned to Egretta garzetta schistacea. Sometimes assigned to asha.
- S8913 See CSR6 and Sheldon (2017).
- T6838 The short-term trend is uncertain but apparently stable. The long-term one is strong increase.
- S8605 An earlier figure of 10,000 was erroneously used based on the same reference.
- T6839 No monitoring data is available. Trend assessment is based on circumstantial evidence. • T6646 - Declines noted in some range states; situation unclear in South Sudan, but high potential there for increasing threat status.
- \$9085 1,958-2,381 pairs reported from AL, BG, GE, GR, ME, RO, TR, UA (BirdLife International 2015), Catsadorakis & Portolou (2017) reported 2,821-3,048 pairs for the same countries based on questionnaire survey to experts and this is used as being the latest estimate. (RU is now entirely allocated to the SW Asian population).
- \$8903 Catsadorakis & Portolou (2017) estimated the population as 4,501-5,870 pairs based on partly old estimates from RU and KZ. This corresponds to 13,500-17,600 individuals after rounding. 9,997 individuals were reported from IR in January 2017 (Amini pers. com).
- T7183 Winter counts show strong fluctuations and the short-term trend is uncertain, the long-term trend is a strong increase. (The trend index represents an increase of 500% since the late
- S8834 Reference updated to provide access to the justification.
- T6798 The short-term trend is uncertain. Therefore, the long-term trend is presented.
- S8832 pairs: 10,000 Senegal Delta, 4,000 PNBA, 6,000 elsewhere
- T6794 Analysis of data from mid-winter counts suggests an increase both in the long- and the short-term (van Roomen et al., 2015, Wetlands International 2017). However, Dodman (2014) asserts that the population has remained rather stable in the 2000s based on breeding numbers, but stability of breeding numbers may reflect only limited availability and knowledge of nesting sites. Therefore, more weight is given to the estimates that suggest an overall increase in population size.
- P1974 Split from Eastern/Southern Africa population in WPE3.
- T6795 Results of the IWC trend analysis are statistically uncertain but the smoothened trend shows a strong declining tendency confirming the assertion of Dodman (2014).
- P1975 Split from Eastern/Southern Africa population in WPE3.
- P1976 This population includes the previous Black Sea/E med and Caspian breeding populations combined. (WPE2)
- S8833 BirdLife International (2015) estimated the European breeding population to be 4,866-5,555 pairs, i.e. c. 15,000-17,000 individuals. This is probably an underestimate as the 1st SE European Pelican Census has recorded 22,944 individuals on 7 May 2016 in the region which is only part of the European range of the species (Alexandrou 2016). It also does not take account of the birds breeding in Central Asia. In the early 1990s, the total Western Palearctic population was estimated at 7,345-10,500 pairs, i.e. 22,000-31,500 individuals. Numbers of P. onocrotalus migrating through Israel was estimated at 70,000 individuals in the late 1980s (Leshem et al. 1996) and, on average, 37,000 between 1990-1999 (Alon et al. 2004, Israel Ornithological Centre, 2009).
- T6797 The European population is increasing both in the short- and the long-term since 1980 (BirdLife International, 2015). No evidence of decline during migration in the 1990s and 2000s (Alon 2004, Israel Ornithological Centre, 2009).
- T6247 New data from Aldabra supports the current trend for the region. The largest colony of birds is found on Aldabra is currently considered stable
- S8246 4,000 pairs on Aldabra and 700-1,100 on Europa; widespread declines in the Indian Ocean.
- T6246 New data inadequate to revise trend. On Aldabra populations fluctuate but seem stable. Significant long-term decline is possible based on historic data.
- \$8835 641,601-683,051 pairs in Europe (BirdLife International 2015). 117,000 pairs in Canada (Chardine et al. 2013). The large increase compared to Berglund & Sundberg (2014) is linked to the treatment of the population in IE and the fact that they have left out the N American breeding population. BirdLife International (2017) estimated that the global population is 1,500,000-1,800,000 individuals. The maximum equals to 2,700,000 individuals.
- T6799 Increasing in all European countries (BirdLife International 2015) and Canada (Carboneras et al. 2017).
- S9086 123,080 pairs.
- T6761 Declined from c. 150,000 pairs in 2005/2006 to c. 135,000 pairs in 2010/2011-2012/2013. Significant long-trem decline from 250,000 pairs in 1956/1957–1968/1969.
- T6245 Trend remains unchanged due mainly to lack of substantive recent census information. However, the population is likely to be in significant long-term decline considering earlier
- S8603 Census of breeding colonies. Crawford (2007) indicates that DuToit et al. (2002) included 238 pairs from one island in error in their estimate of 2665 pairs (8700 birds). Wanless et al. (in prep.) accounted for 3,000 pairs after rounding (1,900 pairs in South Africa in 2013 and 1,200 pairs in Namibia in 2010).
- \$8840 27,451-35,246 pairs in AL, AM, AT, BA, BG, GE, GR, HR, HU, IT, MD, ME, MK, RO, RS, RU, SK, TR and UA (BirdLife International 2015).
- T6807 Both the breeding (BirdLife International 2015) and the wintering numbers (Wetlands International 2017) are increasing.
- S8906 See CSR6 and Sheldon (2017)
- T6808 The IWC trend is rather uncertain, but it does not contradict the earlier assessment of Kreuzberg-Mukhina (2008) and therefore the long-term trend is presented here.
 S8836 BirdLife International estimated the population size to be 33,973-34,386 pairs (i.e. 102,000-103,000 individuals) but this includes also outdated data from the UK. Therefore data from the most recent specialised census was retained (Begnballe et al. 2014).
- T6800 Bregnballe et al. (2014) reported 23% decline between two surveys in 2006 and 2012. This agrees with the short-term trend reported by BirdLife International (2015). However, the population has increased in the long-term (BirdLife International, 2015).
- S8837 Based on Bregnballe et al. (2014) as the more recent count. BirdLife International (2015) data for relevant countries add up to 190,324-216,893 pairs, i.e. 571,000-651,000
- T6801 BirdLife International (2015) reports increase both for the long- and the short-term with indications that the population growth is slowing down. Wetlands International (2017) reports

- S8904 See CSR6 and Sheldon (2017)
- T6803 Wetlands International (2017) reported statistically significant increase over the period of 1990-2015. The trend for the period of 2006-2015 is uncertain due to year-to-year fluctuations, but generally seems to be stable.
- P1529 In WPE2 this population belonged to one single population (Western/Eastern Africa).
- T6804 Wetlands International (2017) reports strong increase in the long-term and statistically uncertain short-term trend showing some decline in the last few years that resulted in a slower but still positive growth rate.
- P1530 In WPE2 this population belonged to one single population (Western/Eastern Africa).
- \$8839 32,217 were counted in January 2014. This counted number was raised to an estimate of 40.000.
- T6805 Both van Roomen et al. (2015) and Wetlands International (2017) suggest increasing population trends. However, the trend is based on only a few years with sufficient data.
- S9087 117,000 pairs
- P1536 Split from Arabian Coast & Gulf of Aden in WPE4.
- P1537 Split from Arabian Coast & Gulf of Aden in WPE4.
- \$9088 2,500 pairs
- . T6987 Declining both in the short- and the long-term.
- S8628 Very low numbers recorded in recent IWC surveys in Sudan, despite reasonable coverage.
- T7027 IWC trend analysis data shows uncertain trend with a positive tendency in the short-term and a stable long-term trend (i.e. between 1996 and 2015). Underhill (2014) suggests that the population has increased by 46% since the early 1980s, which is consistent with the changes in IWC count totals.
- S8955 Updated figures for the European breeding population are 276,969-338,080 pairs. Otherwise, see CSR6.
- T7028 Data based on IWC indicates a stable short-term trend. This followed a subtantial decline from 1990s to the mid-2000s. However, this decline was preceded by a substantial population increase from the 1970s to 1990 (Wetlands International 2017). However, BirdLife International (2015) reports a declining breeding population both in the short- and the long-term. The recent rate of decline is equivalent to 40% over three generations (BirdLife International 2017)
- S8956 The new estimate retained the estimate of van Roomen et al. (2014) that is based on wintering numbers and estimated the maximum value based on the European breeding numbers of 7,150-15,780 pairs (BirdLife International 2015) with some allowances for the breeding pairs in Central Asia.
- T7029 BirdLife International (2015) reported that the populations in RU and TR are declining. This contradicts the results of the mid-winter counts that report stable/fluctuating trend (van Roomen et al. 2014, Wetlands International 2015), which is accepted here because it is based on a better representation of the range.
- T7095 The short-term trend is statistically uncertain but with a growth rate of 1.0013 (SE 0.1023) indicating a stable/fluctuating population. In the long-term, the population has almost doubled since the 1980s although TRIM has assessed the long-term trend as stable. López Gómez et al. (2017) reported redistribution of the population in ZA.
- S8627 January counts include birds from Palearctic, and July counts are always low. This more conservative estimate probably better reflects the former estimate of 25,000 10,000, which was largely based on January data
- S9007 The breeding numbers in BE, DE, DK, EE, ES, FR, LT, NL, PL, PT, SE and UK is 35,480-39,654 pairs, assuming that 60% of the population in ES and 80% of the population in FR belongs to this population. Using a conversion factor of 2.5.
- T7097 Based on winter counts (van Rooment et al. 2015, Wetlands International, 2017). BirdLife International (2015) has assessed the short-term trend of the breeding population in Europe as decreasing with negative population trends in DE, DK, LT, NL and NO. All sources agree that the population has increased in the long-term.
- S9008 8,828-17,345 pairs in AL, AM, AT, AZ, BG, BY, FR, GE, GR, HU, IT, MD, ME, RO, RS, SI, SK, TR & UA. Using a conversion factor of 2.5, this yields an estimate of 22,000-43,000 individuals (BirdLife International 2015). IWC count totals were between 17,000 and 27,000 during the period of 2011-2015 without data from ES, which previously held about 17,000 individuals. Thus the wintering numbers can be estimated to be between 34,000 and 44,000 individuals (Wetlands International 2017) and this new estimate is proposed instead of estimates based on data from the 1990s.
- T7098 Both the breeding and non-breeding data indicate stable/fluctuating population both in the long- and the short-term.
 S8926 See CSR6, BirdLife International (2015) for RU, AM ad AZ, Sheldon (2017) for the rest of the range.
- T7099 In the long-term, the population has declined but not sufficiently to qualify for significant long-term decline.
- T7091 IWC trend analysis shows strong increase both in the short- and the long-term (Wetlands International 2017). López Gómez et al. (2017) suggests that increases and decreases roughly balance each other between SABAP1 and 2 surveys in ZA.
- \$9005 34,866-40,955 pairs in UK, BE, NL, DE, FR, IT, ES, ESIC and PT (BirdLife International 2015). 3,000-5,000 pairs in NW Africa (Dodman, 2014).
- T7092 Both wintering and breeding data show stable short-term trend and strong increase in the long-term
- \$9006 7.996-16.537 pairs in BG, BY, CY, GR, HU, LT, PL, RO, SI, SK, TR and RU (BirdLife International 2015), 220-650 pairs in SE Mediterranean (Snow & Perrins 1998)
- T7093 BirdLife International et al. (2015) reports an annual growth rate of 0.9707-0.9879 in short-term and 0.9894-0.9987 in the long-term. This is driven by a 30-49% decline in the large breeding population of TR, but the numbers increased in the smaller populations of AT, BY, RO, RU and SI. The IWC trend analysis suggests a stable/fluctuating population both in the longand the short-term (1.0056 SE 0.0095 and 1.0034 SE 0.0397; Wetlands International 2017) which is rather close to the trend based on breeding population estimates
- \$8925 9,800-14,700 pairs is South and South-west RU (BirdLife International 2015), assuming that 98% of the RU population is there (Thorup, 2006). Further 1,070-3,200 pairs in AM and AZ (BirdLife International, 2015) and 2,500 pairs in Arabia (Jennings, 2010), 800-1500 pairs in Iran. The partial data adds up to 43,000-66,000 individuals after rounding without including breeding birds from Iraq and Central Asia, where it is a common breeder.
- \$9047 197,509 individuals were counted at the wintering grounds. Rounded to 200,000. However, the breeding range of this population cannot be clearly separated from the one of the population wintering in SW Asia and Eastern and Southern Africa. Hence, estimates of breeding numbers would be not suitable to produce population estimates either. T6990 - Earlier increasing and stable trend turned into a short-term decline between 2006 and 2015.
- \$8378 Tertickiv et al. (1999) estimated the West Siberian population at 230,000-900,000 pairs, but Lappo et al. (2012) considered this to be an overestimate. Based on extrapolation from samples in the SA secton of the Gulf, Zwarts et al. (1991) estimated that 7,000 individuals winter in the Gulf coast of SA.
- T6991 The population is recovering from a long-term decline.
- \$8937 46,089-68,379 pairs in NO, SE (assuming similar numbers as Delany et al., 2009), BY, DE, DK, EE, IE, LT, LV, and the UK (BirdLife International 2015). This yields a post-breeding estimate identical to the one of Delany et al. (2009).
- T7184 The short-term (2000-2012) trend is declining, while the long-term one (1980-2012) is increasing (BirdLife International 2015). This increasing long-term trend assessment contradicts the assessment of the Wader Atlas (Delany et al. 2009) that stated that the population trend as declining based on historical range contraction and declines in southern Sweden and southern Norway as well as a c. 12% decline in the UK between 1994 and 2000 based on information from the Breeding Bird Survey. Because 80-85% of the 'apricaria' subspecies breeds in the UK, the trend in that country has a fundamental influence on the status of the subspecies. As it turns out, the UK reported a 64% increase (!) for the period of 1970-2010 in both EEA (2015) and BirdLife International (2015) while the Wader Atlas has referred to declines of the species from the British uplands in the 1980s and 1990s. However, the 64% increase in the UK is also at odds with other trends reported from the country in other assessments. Tucker & Heath (1994) reported a small decline (i.e. 20-49%) for the period of 1970-1990 and BirdLife International (2004) 12% decline for the period of 1980-2000, while BirdLife International (2015) reported 6% decline for the period of 1998-2010. In the meantime, 21% range loss was reported for the period of 1970-2009 in the UK (EEA 2015). Consequently, the reported increase of 64% in the UK is most likely incorrect. Hence, the long-term trend calculated based on the data in BirdLife International (2015) for this population is also incorrect and there is more evidence in support of maintaining the significant long-term decline assessment for this population as, in the long-term, it has declined in DK, DE, IE, LV, (possibly also in the S parts of NO and SE) and only increased in BY and EE, while the trend is unknown in LT.
- T7156 Little can be concluded based on the change in numbers between the results of the 2003 and 2008 surveys because the counted numbers show increase in IE and the UK, but the WeBS and IWeBS counts show decline (Gillings et al. 2008). It is unclear whether this is a result of redistribution of birds or reflects a real population change. Breeding bird trends are practically unknown (BirdLife International 2015).
- S8939 272,970-373,970 pairs in FI, SE, NO, RU and SJ
- T6989 Overall trend derived from national breeding estimates suggests an increasing short-term and a stable long-term trend. It is increasing in FI, stable in SE, NO and unknown in SJ and
- S8375 Delany et al. (2009) discussed available information. Tertickiy et al. (1999) estimated 800,000-1,500,000 individuals in West Siberia. This figure is significantly lower than the estimate of Byrkjedal & Thompson (1998).
- \$8376 A population estimate for West Siberia of 660,000-1,400,000 individuals by Tertickiy et al. (1999) is considered to be absolutelly unrealistic by Lappo et al. (2012) because it exceeds the global estimate by Delany & Scott (2006). However, the population estimates for the wintering population are also based on meagre data and a large proportion of the population might be missed during IWC counts (Delany et al., 2009). However, significant flocks would have attracted attention of hunters. OSME (2014) considers it a locally common migrant
- P892 Sometimes placed in the genus Charadrius.
- S8946 12,785-48,373 pairs.
- T7011 Declining both in the short- and the long-term.
- T6680 No recent information.
- \$8940 15,585 20,800 pairs in BE, BY, CZ, DE, DK, EE, FR, IE, LT, LV, NL, NO (10%), PL, SE (35%), UA & UK (BirdLife International 2015). IWC count totals were 40,000 48,000 between 2011 and 2015 with 13,000 - 21,000 reported from MA. These numbers include an unknown proportion of individuals from other populations.
- T6992 The species has declined in 6 out of 16 countries and increased only in one. The overall population trend was 0.9840-0.9951 in the short-term and 0.9938-0.9975 in the long-term (BirdLife International 2015). Wetlands International (2017) reported an overall stable population both in the short- and the long-term based on mid-winter counts, but results might be influenced by mixing with other populations of the species particularly in MA that dominates the population trend.
- S8941 206,569 were counted during January counts. Based on presumed underestimations raised to 240,000 birds (van Roomen et al. 2015). This agrees with the lower estimate of Delany et al. (2009) and BirdLife International (2015), but takes also into account the ongoing decline of the population.
- T6993 No trend information is available from the breeding grounds (BirdLife International 2015). van Roomen et al. (2015) assessed the long-term trend as stable and Wetlands International (2017) as uncertain with a declining tendency. Only the long-term trend is reported here because there are only a few years with sufficient data in the short-term
- S9138 Tertickiy et al. (1999) estimated the population in West Siberia at 450-1,000K birds, which Lappo et al. (2012) considers to be an overestimate. Tomkovich & Mischenko (in litt, 2014)

- T6994 The breeding population has declined marginally (0.997) in the short-term and was stable (1.001) in the long-term.
- S8928 48,809 137,229 pairs in Europe (BirdLife International 2015). See also CSR6 and Sheldon (2017).
- T6995 Stable/fluctuating trend both in the short- and the long-term.
- P831 Includes proposed tephricolor.
- S8630 estimates include 50,000 for Southern Africa (Underhill et al. 1999) and 10,000-20,0000 for Tanzania (Baker 1997)
- T6996 Statistically uncertain moderate decline both in the short and the long-term.
- T6997 The overall long-term trend is a statistically significant moderate decline, driven by a steep decline until about 2009, followed by some recovery.
- S8756 Tree, T. In litt.2008. Considered the upper limit presented in WPE4 to be too high.
- P857 In WPE4, subspecies was considered "mechowi", but Delany et al. (2009) treated as "mechowi/tenellus". Treated by some authors as "hesperius".
- P859 Includes "nigirius" & "spatzi". In WPE3, this subspecies was considered "hesperius". In WPE4, the population was "mechowi, W to Central Africa"
- S8943 The total of national breeding population estimates in AT, BE, DE, DK, ES, ESIC, FR, GIB, HU, IT, NL, PL, PT, PTAC, PTMA, SE, SI and SK is 8,813-24,006 pairs (BirdLife International 2015). According to Dodman (2014) 10,000 pairs can be added to this for Northwest Africa. van Roomen et al. (2015) reported 45,000 wintering birds. The IWC count totals ranged only between 12.500-33.500 individuals in recent years (Wetlands International 2017)
- T7002 Both breeding (BirdLife International 2015) and non-breeding numbers (Wetlands International 2017) indicate that a stable or still moderately declining population following significant long-term decline. The trend assessment has changed drastically compared to CSR6 and van Roomen et al. (2015) because the data from Morocco (which holds a very large proportion of the wintering population) was not available for the earlier trend analyses.
- \$8944 11,213-16,236 pairs in Europe (BirdLife International 2015). Based on Snow & Perrins (1998) breeding numbers in IL, JO and EG are estimated at 3,800-5,700 pairs. This yields a total of 15,013-21,936 pairs.
- T7003 Breeding numbers are reported to be moderately declining in 3 out of 8 countries including TR with the bulk of the population and not increasing anywhere. The overall population trend is 0.993 both in the short- and the long-term (BirdLife International 2015). Trends based on mid-winter counts show large fluctuations (Wetlands International 2017).
- \$8929 1,520-4,540 pairs estimated for the European part of the range (BirdLife International, 2015). Further 30,000 pairs estimated for Arabia but no estimates are available for Central Asia (Sheldon, 2017). The new lower estimate is based on sum of the minimum estimates for Europe and Arabia with some allowance for other parts of the range. The higher estimate makes allowances for the population with unknown size in Central Asia.
- S8696 Simmons (2002) gave estimate of 11,200, whilst Simmons et al. (2007) gave 11,500 based on later counts.
- T7005 Long-term trend is strong increase based on the IWC counts, but may only reflect better counts. Short-term trend is uncertain or declining depending on the statistics used for assessment.
- S8760 Simmons et al. 2007. A coordinated census in January 2005 resulted in a more accurate and precise estimate.
- S8945 Counts at Barr al Hikman, OM, alone exceeded 123,000 individuals in January 2016 (de Fouw et al. 2017). Zwarts (1991) estimated the population wintering along the Gulf coast of Saudi Arabia at 28,000 individuals. Another 13,000 can be estimated to winter along the Red Sea coast of Saudi Arabia based on the counts of Nagy et al. (2014). Dodman (2002) estimated that at least 20,000 winters along the Red Sea and Indian Ocean coast of Africa. Balachandran (in litt. 2005 cited by Delany et al. 2009 and Dodman 2014) estimated another 100,000 individuals for India. This adds up to 284,000 individuals. Considering the uncertainty involved with summarising estimates over such a long period, a new estimate of 250,000-300,000 individuals is given
- S8930 600-1,000 pairs in TR (BirdLife International, 2015), 500 pairs in the extended Arabian Peninsula (Sheldon, 2017).
- P879 Name crassirostris is invalid because it is preoccupied (see Carlos et al. (2012). Birds in Azerbaijan & Armenia identified as belonging to this subspecies by Hirschfield et al. 2000.
- S8931 Zwarts et al. (1991) estimated 9,000 for the Saudi Arabian Gulf coast, Fouw et. al (2017) c. 15,000 at Barr al Hikman, up to 8,000 in IR in 2009 and up to a few thousands in other Gulf countries. Only a few hundred reported from the Red Sea, but the area is very incompletely surveyed (Wetlands International 2017). Based on surveyoing 7% of the Red Sea coast of Saudi Arabia (Nagy et al. 2014), the wintering numbers can be estimated to be around 5,000 individuals there. Assuming similar numbers for the African coast of the Red Sea and deducting the estimates for the columbinus subspecies results in a lower estimate of 35,000 and a provisional upper estimate of 50,000 is proposed to make allowances for Yemen and Somaliland.
- T7009 Possibly also increased in the long-term.
- T7010 The population is recognised to be in significant long-term decline based on Stroud et al. (2002). It is now considered to be regionally extinct from Europe (BirdLife International 2015), whereas populations in the core of the range is thought to be fairly stable (Wiersma et al. 2017).
- P904 Merged with Europe/Europe & North Africa population in WPE5, following proposal in CSR5. Review published in 2009 Wader Atlas suggests mixing of populations in all seasons to an extent that makes separation invalid.
- P2432 Europe/Europe & North Africa and Western Asia/South-west Asia populations merged to Europe, W Asia/Europe, N Africa & SW Asia in WPE5, following proposal in CSR5. Review published in 2009 Wader Atlas suggests mixing of populations in all seasons to an extent that makes separation invalid.
- \$8935 1,593,849-2,584,810 pairs in Europe (BirdLife International, 2015). According to Dodman (2014), c. 100 pairs in Morocco. In SW Asia, up to 90,465 birds (2003) were counted during IWC counts and part of the birds winter to the west of the region (Wetlands International, 2014). However, there is no sufficient new information to improve of the current estimate
- T6988 IWC data shows moderate short-term decline that followed strong increase to the mid-1990s (Wetlands International 2017). BirdLife International (2015) shows strong decline in breeding numbers both in the long-and short-term. Based on the latter and considering the uncertainties associated with the IWC data for this species which also winters on agricultural areas normally not included into the IWC counts, the trend in breeding numbers is used to qualify the population being in significant long-term decline.
- S8936 1,070-1,620 pairs in TR, CY and GR (BirdLife International 2015), but the bulk of the population in Egypt and Israel (Delany et al. 2009)
- T7185 Currently stable in TR, GR and increasing in CY.
- S8689 Bos et al. 2006. Samples of rice fields in Senegal, Gambia, Guinea, Guinea Bissau & Sierra Leone resulted in an estimate of 44,000 for these areas alone. However, this was V. senegallus. Thus estimate reversed to Dodman 2002.
- · P944 A partial altitudinal migrant, moving to lower areas after breeding.
- T7186 No changes in the number of quarter degree grid cells where the species was absent or reporting rate declined compared to the number of cells where the species was recorded newly or reporting rate has increased between SABAP1 and 2 based on data from the SABAP2 portal (ADU 2017).
- T7187 Reporting rate has declined in two-third of quarter degree grid cells and increased only in about one-third of quarter degree grid cells between SABAP1 and 2 based on data from the SABAP2 portal (ADU 2017). However, this may reflect the situation only in the southern part of the range. Based on this partial information, the species should be precautionally considered being in significant long-term decine
- P948 Often included in coronatus.
 S8748 Tree, T. In litt. 2008. Not as widespread in Botswana as previously assumed.
- T7188 The number of quarter degree grid cells with declining and increasing reporting rates are roughly the same.
- S8695 Dodman (2014) has increased estimate based on Bos et al. (2006).
- T7189 The number of quarter degree grid cells where the species has declined was 62% compared to 38% where it has increased in Southern Africa, Based on this, the population is considered being in significant long-term decline.
- P2462 The former Central Asian Republics/NW India and SE Europe & Western Asia/North-east Africa populations were merged after WPE5 following a review by the AEWA Technical Committee. See www.unep-aewa.org/en/document/delineation-biographic-populations-sociable-lapwing-vanellus-gregarius
- T7190 Significant long-term decline is still maintained.
- P953 Often assigned to genus Chettusia. merged with the Central Asian Republics/South Asia population in CSR7.
- P954 Merged with the SW Asia/SW Asia & North-east Africa population in CSR7.
- P2463 The former SW Asia/SW Asia & North-east Africa and the Central Asian Republics/South Asia populations were merged in 2017. See justification at http://www.unep-aewa.org/sites /default/files/document/aewa_stc_12_12_population_delineations_rev1_0.pdf. The population is assigned to the Central Asian flyway as majority of the birds migrate to India
- P506 In WPE2 this population belonged to one single population (Europe/Western Africa).
- S9019 In BY, EE, FI, LV, NO, European RU and SE, 90,943-149.940 pairs.
- T7113 BirdLife International (2015) estimated that the breeding numbers are stable/fluctuating both in the long- and the short-term. An increase is estimated in the combined numbers of this and the islandica subspecies based on mid-winter counts (van Roomen et al. 2015).
- \$8308 See Delany et al. 2009. Tertickiy et al. (1999) estimated the population in the Yamalo-Nenetsky Autonomous Area at 900,000-1,900,000 individuals. Lappo et al. (2012) considers this to be an overestimate
- T7114 Both the long- and the short-term trends are uncertain, but TRIM assessed the long-term trend as stable.
- P509 Recently revived subspecies (Engelmoer & Roselaar (1998)). In WPE2 this population belonged to one single population (Europe/Western Africa).
- \$9020 Thorup (2006) estimated the population size to be 250,000 pairs, which was maintained as the current estimate in the European Red List of Birds (BirdLife International et al., in prep.). T. Gunnarsson (in litt., 2014) suggested that 200,000 pairs is a safe estimate. However, winter counts account for only 131,865 phaeopus and islandicus combined (van Roomen et al. 2014).
- T7192 Trend information for breeding numbers is only available from the UK which supports a very small part of the population (BirdLife International 2015). The wintering population mixed with phaeopus is increasing (van Roomen et al. 2015) but the two populations cannot be separated. In the past, the population was though to be stable (Delany et al. 2009) therefore it is not considered to be in significant long-term decline.
- T7227 Significant long-term decline maintained based on Morozov (2000). Current trends are not known. A small wintering population was rediscovered in Mozambique (Allport & Cohen 2016), but breeding birds were not found at the visited breeding sites in 2016 (V. Morozov pers. com. 2016).
- P2458 Population added for WPE6, following Van Gils et al. (2016) www.hbw.com/node/53894
 S8692 The population is assumed to be tiny (fewer than 50 individuals and mature individuals) based on small number of recent records, most of which are of just 1-3 individuals (BirdLife International, 2014). The maximum value only corresponds to the upper threshold for Critically Endangered species under the IUCN Red List criteria.
- T6684 The last undisputed record with sufficient evidence for incontrovertible identification was on February 1995 in Morocco, despite subsequent intensive searches of the non-breeding range (Crockford in litt., 2014).

- \$8312 Perennou et al. (1994) Tertickiy et al. (1999) estimated the population in the Yamalo-Nenetsky Autonomous Area at 90,000-350,000 individuals based on transect counts, but Lappo et al. (2012) considers this to be an overestimate
- T7117 Increasing trend is apparent in mid-winter count data, but it is unclear whether this is due to range shift or reflects genuine change. The latter would contradict other available information reviewed by Delany et al. (2009).
- P536 Population added in WPE3.
- T7194 Although current trend is unknown, evidence for significant long-term decline is reviewed in Delany et al. (2009).
- S9018 Since 2011, every year, IWC count totals have exceeded the estimate of 120,000 and in two years they were also above 140, 000 (Wetlands International 2017). BirdLife International (2015) estimated the European breeding population at 25,008-25,012 pairs, i.e. some 75,000 individuals that is much lower than the count totals.
- T7110 The trend is increasing both on the basis of breeding and wintering numbers.
- \$9048 497,433 individuals counted in the wintering range. Rounded to 500,000 individuals.
- T7111 Only a few datapoints are available with sufficient data, but this indicates a decline both in the long- and the short-term.
- S8306 See overview in Delany et al. 2009. The Bar al Hikman supports a large proportion of this population (e.g. 87,187 individuals in Dec. 2013, de Fouw in litt.). Tertickiy et al (1999) estimated the population in West Siberia at 500,000-1,800,000 individuals based on transect counts, but Lappo et al. (2012) considers this unrealistic.
- T7112 Increasing both in the long- and the short-term but mainly based on counts at Barr al Hikman, which appears to be the key site for this population
- S9015 41,048-66,536 pairs based on national estimates (BirdLife International 2015). Applying a conversion factor 2.1 (based Hooijmeijer in litt, 2014), this is equal to c. 86,000-140,000 individuals. Kentie et al. (2016) have estimated the population size of the Dutch population based on resighting and produced an estimate of 33,000 (26,000-41,000) pairs. The estimate is based on assuming that this represents 87% of the population.
- T7106 Significant long-term decline.
- S9016 36.395-57.360 pairs and using a multiplier factor of 2.1.
- T7107 The population has declined both in the long- and the short-term.
- S9139 Perennou et al. (1994). Recent maximum of annual count totals was 33,265 individuals in Jan. 2013 in IR.
- T7108 Significant long-term decline based on IWC data. The short-term trend is uncertain due to a very large count in 2013 which has great influence on the short-term trend.
 S9017 Breeding numbers are estimated at 25,008-25,012 pairs by BirdLife International (2015). This is certainly an underestimation because the estimate for IS is still based on Thorup
- (2006), which should be considered to be outdated. IWC count totals were between 70,000 and 94,000 during the period of 2011-2015 without ES (Wetlands International 2017). This would be roughly consistent with projecting from the earlier estimate of 50,000 - 75,000 individuals of Gill et al. (2007) that would yield an estimate of 90,000 - 134,000 individuals assuming 6% annual growth rate for the last 10 years based on the IWC trend analyses (Wetlands International 2017).
- T7109 The population has increased both in the long- and the short-term based on both the wintering (Wetlands International 2017) and on the breeding (BirdLife International 2015) trend estimates
- \$9034 15,911-37,085 pairs (BirdLife International 2015), van Roomen et al. (2015) accounted for only 22,000 individuals at the wintering grounds but this species extensively uses poorly counted non-eastuarine coast.
- T7135 Both breeding and non-breeding trends show long-term declines, which appear to have slowed down in recent years according to BirdLife International (2015) and Wetlands International (2017), but van Roomen et al. (2015) assessed the trend as uncertain although also showing a negative tendency.
- S8334 See Stroud et al. (2004). Tomkovich & Michenko (in litt, 2014) think it can be even more.
- T7136 Short-term trend is uncertain. The population is in significant long-term decline.
- S8335 Only 107 counted at Bar al Hikman in Dec. 2013 (de Fouw, in litt) and they estimated a maximum of 1000. Recent maximum was 488 individuals in IR. 10 individuals in UAE Jan. 2013. None observed at the Tarut Bay and surrounding areas in Jan. 2014 (Nagy et al., in prep.).
- T7195 The result of the IWC trend analysis is uncertain but count totals suggest a decreasing tendency. This is consistent with the references mentioned in CSR6.
- S9035 249,614 individuals at the wintering grounds. Rounded to 250,000 birds.
- T7138 van Roomen (2015) estimated a strongly declining trend and suggest that only half of the numbers of the 1980s remained. Wetlands International (2017) estimated the long-term trend being stable. The differences result from different site selection, imputing and trend analysis methodologies
- \$9156 The total of the national wintering population estimates from IE, UK, PT, ES, FR, BE, NL, DE and DK is 504,907-564,915 individuals (BirdLife International 2015). IWC count totals fluctuated between 273,000 and 423,000 during the period of 2011-2015 (Wetlands International 2017).
- T7137 The short-term trend is 0.9923 (SE 0.0314). The long-term trend is increasing.
- S9044 265,391-1,653,224 pairs with a drastically increased 1,600,000 estimate for European RU.
- T7153 Breeding numbers are decreasing in almost every country except LT, where increasing, BY, RU where fluctuating and LV where unknown (BirdLife International 2015). Verkuil et al. (2012) raised the possibility that the observed decline in Europe is the result of range shift.
- \$8356 See discussion in Delany et al. (2009). Tertickly et al. (1999) estimated 4.2-7.0 million individuals in the Yamal-Nenets Autonomous Area, which Lappo et al. (2012) considered to be an overestimate. Tomkovich (in litt).
- T7154 IWC trend analysis produced a very uncertain trend showing a very strong increase (>10% per annum), which is biologically very unlikely (Wetlands International 2017), but might be consistent with the Verkuil et al. (2012) theory of range shift.
- S9142 29.650-44.050 pairs, i.e. 89.000-132.000 individuals.
- T7196 The short-term trend is unknown in FI, NO, RU, stable in SE. Based on 30-40% decline in FI (hosting 82% of the population) significanthe long-term decline (BirdLife International 2015)
- T7145 Significant long-term decline.
- T7197 Nagy et al. (2014) found very rapid decrease (7.88±1.86%) between 2003 and 2012. However, the range of this population is not very well covered, particularly in the Red Sea and southern Gulf. de Fouw et al. (2017) found decreasing numbers at Barr al Hikman, but noted some uncertainties. • S9093 - 8,100-16,600 pairs, i.e. 24,000-50,000 individuals, in NO, FI, SE (BirdLife International 2015) following the treatment of national populations of Delany et al. (2009).
- T7143 Unknown in NO and FI, but the larger population in SE considered to be stable. Possibly declined in FI in the long-term, which would qualify the population being in significant longterm decline (BirdLife International 2015). The IWC trend analysis has produced uncertain results (Wetlands International 2017).
- \$8343 Mischenko (2004) estimated the breeding population in European RU at 40,000-120,000 pairs. Tertickiy (1999) estimated numbers in West Siberia at 1-2 million individuals Tomkovich & Mischenko (in litt., 2014) also suggested these numbers. • \$9036 - 193,418 individuals at the wintering areas in the 2010s. Rounded and raised to 200,000 (van Roomen et al. 2015). The European breeding population is estimated at 25,100-50,100
- pairs (BirdLife International 2015), which agrees rather well with the estimate based on wintering numbers considering that some of the birds breeding on Taymir also partly allocated to this
- population. T7139 - After strong increase, the population seems to have stabilised.
- T7140 Long-term trend is probably stable and the decline might be just part of the fluctuation.
- \$9040 140,000-265,000 breeding pairs from NO, SE, FI and European RU (BirdLlfe International 2015)) including a new estimate of 100,000-200,000 pairs for RU. However, Lappo et al. (2012) notes that this might be still an underestimate because Morozov and Syroechkovskiy (2004) estimated 175K breeding pairs on Kolquev and Morozov (1999) 2,800-3,000 pairs on Vaigach. The total of national estimates of wintering birds in PT, ES, IT, SL, HR, FR, BE, NL, UK, DK and DE is 1,126,816-1,402,364 individuals (BirdLife International 2015), i.e it is largely in
- the same range as the estimate of Stroud et al. (2004).

 T7148 Stable in the long-term. Slight decline in the short-term.
- P657 Occasional breeder in SE Greenland (Boertmann (2002)).
- \$9041 725,305 individuals counted in the 2010s. Rounded to 730,000 for minimum estimate and some allowance made for uncertainties in the upper one.
- T7150 Only a few datapoints are available, van Roomen et al. (2015) assessed the long-term trend as slightly declining, but noted that datapoints are sparse and the decline is based only on the 2014 count. Wetlands International (2017) has got very similar results, but the long-term trend assessment was stable.
- P658 In WPE2 this population belonged to one single population (Baltic/UK/Ireland).
- S9042 472-598 pairs.
- T7151 Decreasing in every country except in FI. Unknown in LV. Significant long-term decline.
- P659 In WPE2 this population belonged to one single population (Baltic/UK/Ireland).
- \$9043 8,750-10,750 pairs from the UK and IE.
- T7152 55.5% increase in the UK during the period of 1998-2010, 27% decrease in IE during the period of 1996-2008. T7198
- - BirdLife International (2015) reports unknown trend. Delany et al. (2009) provides a review of available information. P641 -
- There is considerable variation in this form and there is potential to identify up to four populations (Stroud et al. 2002).
- \$9039 16,705-32,930 pairs in European RU, SJ, NO, FI, SE (BirdLife International, 2015 tWest Siberian population is little known, but 1,000-5,000 individuals were estimated for the Severnaya Zemlya alone (Lappo et al. 2012).
- T7146 Breeding trend is unknown except NO where it is thought to be stable (BirdLife International 2015). IWC trend shows strong increase (Wetlands International 2017).
- \$8345 Revised estimates for the UK 75% of 13,000 individuals (Musgrove, 2011) and 470 individuals for IE (Crowe & Holt, 2013) and 500-1,200 on FO (BirdLife International, 2004) suggest a total of 11,000-11,500 individuals.
- T7147 Steep decline since 1991. Andres et al. (2012) also suggests decrease for the population based on CBC counts.
- \$9037 270,828 individuals at the wintering areas. Rounded and raised to 300,000 (van Roomen et al. 2015). Breeding population in NO, FI and RU is 48,200-76,005 pairs (BirdLife International 2015), i.e. 144,600-228,000 individuals. • T7141 - Lappo et al. (2012) suggested that the breeding population in RU is stable. However, IWC trend analyses indicate decline both in the short and the long-term (van Roomen et al.
- 2015, Wetlands International 2017).
- \$8341 Tertickiy et al. (1999) 4.3-6.3 million in West Siberia. Lappo et al. (2012) considers it to be a massive overestimate, but considers the estimate of 1.0 million as an underestimate

decreasing by 5-30% in RU (hosting 84% of the population) and in CH, SI, SK, TR and UK (<5% in total). The population is thought to be stable in CZ, DK, FI, LI and LV (<5% in total), stable in DE, EE, ES, FR, GR, LT, RS and SE (the latter hosting about 8% of the population), fluctuating in BA and UA, unknown in AD, AL, AT, BG, HR, HU, IE, IT, LU, ME, MK, NL, NO, PL, RO and XK. Only two countries, FI and FR classified the quality of their long-term trend assessment as good, the rest is medium or poor (BirdLife International 2015). The significant long-term decline assessment depends primarily on the poor quality assessment of RU. Delany et al. (2009) has reviewed earlier claims of decline in RU and other evidence and considered the population remaining relatively stable also in the long-term following the assessments of Stroud (2004) and Ferrand et al. (2006).

- P448 Presumed to breed predominantly in western half of Siberia.
- \$9011 6,300-17,300 pairs.
- T7102 Stable in SE unknown in the larger NO population.
- \$9012 55,352-127,017 pairs in Europe, but size of the population in West Siberia is unknown.
 \$77103 2000-2012: 0.9899 0.9951, 1980-2012: 0.9968 0.9985. The rate of decline in the long-term is lower than what is required for significant long-term decline.
- \$9013 2,484,817-4,866,803 pairs
- T7104 Stable in the short-term and in significant long-term decline based on breeding numbers. The European population is estimated to be decreasing at a rate less than 25% in 14.4 years (i.e. by c. 2.2% annually). The national population has declined in AT, BE, CH, CZ, DE, DK, ES, FI, FR, IE, LI, LT, NL, PT, RU, SE, SK, UK representing over 90% of the European population, increased only in LV and PL, stable in RO and TR (BirdLife International 2015). The IWC trend analysis shows a strong increase followed by some decline (Wetlands International 2017). However, the IWC is not well suited to monitor this cryptic species.
- T7199 The IWC trend analysis shows an uncertain trend with a strong increasing tendency, but it is probable that this is just an artefact of the null-allocation procedure in case of this easy. to-overlook species
- S9014 Including 6,900 pairs for Orkney and Shetland following Delany et al. (2009).
- \$9010 19,630-44,086 pairs in Europe (BirdLife International 2015) which is considerably smaller than the 2.5-3 million individuals estimated by Kalchreuter (2002) based on harvest data. Therefore the earlier estimate is retained following Delany et al. (2009).
- T7101 Each country reported stable population trend to BirdLife International (2015).
- \$8299 Tertickiy et al (1999) estimated 310-660K in W Siberia. Bukreev & Sviridova (2006) estimated 600-900 pairs in IBAs that occupied 3.4% of the area.
- \$9045 295,080-639,174 pairs estimated in Europe. That alone would yield an estimate of 885,000- 1,918,000 individuals estimate.
- T7200 Only decreasing in the UK, stable in NO, SJ, SE and RU, unknown in FI, GL and IS (BirdLife International 2015).
- S8358 95% confidence interval around 1,617,000 individuals estimates derived from incomplete PRISM surveys.
- T7155 No information on long-term trend exists, although changes at individual Arctic study sites indicate an apparent decline in Canada (Andres et al. 2012). Trend in Europe unknown (BirdLife International 2015).
- P582 Often placed in genus Tringa, and often given the specific name terek.
- \$9031 15,453-50,706 pairs in Europe (BirdLife International 2015). Tertickly et al. (1999) estimated the population in the Yamalsk-Nenets Autonomous Area at 280-650 individuals, but this represents only a small part of the range beyond the Ural.
- T7131 BirdLife International (2015) assessed the short-term trend as declining based on estimates from RU and FI. Trend based on small number of birds counted during the IWC suggests stable trend (Wetlands International 2017) although a negative trend could be also observed up to the mid-2000s.
- P585 Often placed in genus Tringa.
- S9032 337,082-546,718 pairs in Europe without RU, TR and UA. (Calculation error in CSR6).
- T7132 Breeding numbers indicate decline both in the long- and the short-term (BirdLife International 2015, EBCC et al. 2016). The trend based on mid-winter counts indicates a stable long-term trend with a negative tendency until 2012 (Wetlands International 2017).
- \$9033 457,000-913,600 pairs in AM, AZ, RU, TR and UA (BirdLife International 2015). 125,000-240,000 pairs in the Yamalo-Nenetsky Autonomous Area (Tertickiy et al. 1999), but this represents still only part of the breeding range
- T7133 Trend in European RU is estimated to be stable (BirdLife International 2015). This is consistent with the results of the trends based on mid-winter counts (Wetlands International
- \$9029 615,512-1,049,906 pairs
- T7127 BirdLife International (2015) reports stable short-term and increasing long-term trend based on breeding estimates. This agrees with EBCC et al. (2016) and with the results of midwinter counts (Wetlands International 2017).
- T7128 The short-term trend is uncertain, but the long-term trend is significant long-term decline.
- S9022 20,500-54,000 pairs in NO, SE, Fl and RU.
- T7118 Breeding populations trends are declining (SE), unknown (NO and RU in the short-term) or fluctuating (RU in the long-term) with the exception of FI, where it is considered to be stable both in the long- and the short-term (BirdLife International 2015). EBCC et al. (2016) indicates declining trend of the breeding population. The IWC trend analysis suggests stable (van Roomen et al. 2015) or declining (Wetlands International 2017) trend.
- \$8315 Perennou et al. (1994). Tertickiy et al. (1999) estimated the population in West Siberia at 400,000-1,300,000 individuals based on transect counts, but Lappo et al. (2012) considers this to be an overestimate.
- T7158 TRIM classified both the short- and the long-term trend as fluctuating
 S9028 73,709-127,427 pairs in BY, EE, FI, LT, LV, NO, SE, UK.
- T7125 The trend of the breeding population is stable in the short-term and increased in the long one although the trend of the sizeable NO population is unknown. van Roomen et al. (2015) assessed the wintering population as increasing in the long-term (2%) while Wetlands International (2017) as stable although the population might have increased by 44% (n.s.) between 2007 and 2015.
- S9129 Stroud et al. (2004). Tertickiy et al. (1999) estimated the West Siberian population a 200,000-400,000 individuals, but Lappo et al. (2012) considers this a likely overestimate.
- T7126 IWC trend is stable with a negative tendency (Wetlands International 2017). Lappo et al (2012) suggest that the population is declining.
- \$9023 45.500-69.000 pairs in NO. SE, FI (BirdLife International 2015). An additional 800-4.500 pairs added based on Thorup (2006) for RU, van Roomen et al. (2015) has accounted for 140,000 individuals at the wintering grounds in the 2010s.
- T7119 Both breeding and non-breeding numbers indicate a stable/fluctuating trend in the short-term (BirdLife International 2015, van Roomen et al. 2015). The assessment of the long-term trend is problematic. Based on the data presented in BirdLife International (2015) the population is assumed to be in significant long-term decline at a rate of c. 2.7%. However, the status of this population is rather unclear. Delany et al. (2009) assessed the trend being stable based partly on the reportedly stable trend in Norway which is now thought to have declined by 25-50% between 1980 and 2012 although it was also assumed to be stable also between 1970 and 1990 (Tucker & Heath 1994). The trend based on wintering bird is reported as stable (annual growth rate 1.01) by van Roomen et al. (2015) who fitted essentially a linear trend over rather fluctuating imputed count totals between 1979 and 2014. However, the trend-line seems to be strongly influenced by a couple of low counts at the beginning and some high counts at the end of the trend period. Otherwise, the data points show a declining tendency. In addition, the winter counts include an unknown number of birds from other populations.
- P552 Population added in WPE3. Nominate Common Redshank populations in Europe will probably be re-divided in future into N Europe (bre) and Central & E Europe (bre) populations.
- \$9024 121.179-221,120 pairs in continental Europe (BirdLife International 2015) Assuming, based on Thorup (2006), that 75% of the bird in European RU belong to this population and following the 50% reduction for TR, both suggested by Delany et al. (2009).
- T7120 The breeding populations has declined both in the short- and the long-term.
- T7121 The short-term trend is possibly uncertain. The long-term trend shows a strong increase, but this is probably just the consequence of better counts. Based on the available data, the long-term trend cannot be established.
- S9025 BirdLife et al. (2015) maintained the estimate in Thorup (2006). However, this contradicts winter counts, which are much lower. See discussion in Delany et al. (2009). Therefore, that estimate is retained here.
- T7122 No trend data from breeding ground, wintering population is mixed with (britannica) and the combined trend shows large decline (Nagy et al., 2014, van Roomen 2015). It is unclear whether this decline reflects change in the (britannica) subspecies only or in both subspecies.
- P555 Included in robusta in WPE2.
- S9026 25,500 pairs in UK and IE
- T7228 Declined by 35% in the UK during the period of 1998-2010 and by 88% in IE during the period of 1991-2008 (BirdLife International 2015).
- S9030 463,101 770,208 pairs in Europe without RU.
- T7129 Stable trend based on breeding data (BirdLife International 2015, EBCC et al. 2016). The trend based on wintering numbers is a strong increase (Wetlands International 2017), but the trend based on breeding numbers is considered more reliable in case of this species that is rather dispersed at the poorly covered wintering grounds in Africa.
- \$9094 300,000-750,000 pairs, i.e. 900,000-2,250,000 individuals, in European RU (BirdLife International 2015). Otherwise see CSR6.
- T7130 Declining both in the short- and the long-term. The geographic pattern of national trends suggests range shift.
- S9027 12,070-30,268 pairs in BY, EE, FI, LT, LV, PL, RO, RU, SE and UA.
- T7123 Only reported to decrease in EE, increased in BY, LT, LV, stable or fluctuating in PL and SE, but unknown in RU, Fl and RO. Trend based on IWC data is also uncertain.
- T7012 See also CSR6.
- S8947 3,381-3,906 pairs in ES, PT, FR and IT (BirdLife International 2015). Dodman (2014) estimated 6,000-9,000 pairs in NW Africa
- T7016 Increasing in FR and PT, fluctuating in ES (European Topic Centre on Biological Diversity, in prep.) and unknown in IT and NW Africa.
- S8948 2,932-6,491 pairs in Europe (BirdLife International 2015). Another 2560-2610 pairs in the E Mediterranean, mainly in EG (Snow & Perrins 1998)
 T7017 Trend based only on European part of the range (BirdLife International 2015). Decline is also reported from the Asian part of the E Mediterranean (Maclean & Kinwan 2017). Based on
- this, the significant long-term decline is likely to continue. • S8927 - C. 3000 pairs in Europe (BirdLlfe International 2015) assuming 50% of the minimum estimate for RU belongst to this population. Sheldon (2017) estimates 20,000 pairs in IQ and
- 1000-1500 pairs in IR. No estimates available for Central Asia

- T7020 BirdLife International (2017) and Delany et al. (2009) assume that decline has taken place due to habitat loss.
- T7019 BirdLife International (2017) and Delany et al. (2009) assume that decline has taken place due to habitat loss.
- T6251 New data inadequate to revise trend which remains unknown.
- T6252 New data inadequate to revise trend which remains unknown. On the Seychelles numbers are increasing but more surveys are required to establish a trend [50]. No trend estimate is available for Mauritius.
- T6716 Due to small sample size (only 7 sites), the trend based on mid-winter counts is uncertain (Nagy et al., 2014, van Roomen et al., 2014).
- S8977 23,689-45,228 pairs
- T7054 Descreased in the short-term, increased in the long-term.
- P1120 Winter range of E Siberia breeders is poorly known.
 S8426 Unknown numbers breed in Central Asia and West Siberia. 52,769 counted in the Nile Delta in Dec-Jan 1989/1990 (Olsen 2010).
- T7055 Significant long-term decline, but only a few datapoints after 2006.
- P1130 Balmer et al. (2013) showed strong exchange between colonies in the NW and NE Atlantic and the whole R. t. tridactyla subspecies should be treated as one population. These populations have been treated together since CSR4, but the change has not been reflected in WPE5.
- T6272 Signs of decline though recent increase on Greenland.
- \$8595 Veen (in litt. 2014) has estimated that the population consists of 8,000-10,000 pairs based on Veen et al. (2007) and Veen et al. (2011). 17,332 individuals counted in January, rounded to 20,000 (van Roomen et al., 2014).
- T7051 Wetlands International (2017) assessed the trend as moderate decline based on the TRIM assessment. This differs from the results of van Roomen et al. (2015). The difference might be just caused by applying different trend analysis methods.
- S8974 35,604-57,035 pairs in Europe (BirdLife International 2015). 4,225 nests in EG (Dodman, 2014), 3,000-4,000 pairs in TN, 12-24 pairs in MA, possible breeds in DZ (BWPi, 2006).
- T7052 Trends based on both breeding and wintering seasons indicate decline in the short-term. In the long-term, the IWC trend analysis (Wetlands International 2017) suggests strong increase, while the BirdLife International (2015) reports that the breeding numbers are decreasin in Europe in the long-term. However, this is based on data from RU and UA. Considering the methodological challenges monitoring non-breeding gulls, the long-term trend based on breeding numbers are accepted.
- S8975 The IWC count totals were around 24,000-56,000 individuals between 2011-2015 (Wetlands International 2017).
- T7201 Both the short- and the long-term trends are uncertain.
- \$8972 915,655-1,185,811 pairs
- T7048 The short-term trend is stable with a declining tendency based on both the breeding and mid-winter count data. Significant long-term decline since the 1980s based on both breeding and wintering numbers.
- \$8973 420,710-801,605 breeding pairs in BG, BY, GR, RO, RU and TR.
- T7049 Also stable in the long-term
- S9140 Most recent maximum annual count total in SW Asia was 74,828 individuals in 2011. Overall, the sum of the site level 5-year-means was 105,311 individuals in SW Asia for the period of 2008 and 2012, but this has not included SA and OM. Nagy et al. (in prep.) counted 11,902 individuals at Sabkhat al Fasl and Tarut Bay and 333 along c. 7% of the Red Sea coast (equivalent to some 4,700 if extrapolated for the whole SA section of the Red Sea coast) in SA in Jan. 2014.. 5,760-6,222 individuals in Uganda in 2006-2007. Otherwise, totals from E Africa are under a thousand birds. These suggest that the estimate of Perennou et al. (1994) is still valid.
- T7050 Also stable in the long-term.
- P1091 Sometimes considered conspecific with L. novaehollandiae
- \$8632 The former estimate of 30,000 is given as a range, which is more appropriate as breeding data on which the 30,000 was based came from a range of different years / decades.
- T7047 Possibly declining in the short-term, but this seems to be part of a long-term fluctuation. Overall, still a strong increase in the long-term despite of the recent decline.
- S8594 23,,428 individuals counted in January. Rounded and raised to an estimate of 25,000 30,000.
- T7160 Unclear trend on the basis of trend analyses with a tendency of decline, which is confirmed by a small decrease in estimated population size population estimates stable numbers (van Roomen et al. 2015). Wetlands International (2017) has found uncertain strong increase in the long-term which apparently slowed down in the short one.
- P1085 Split from C, E & S Africa population in WPE4 by mistake. Terminated based on decision of AEWA MOP6
- P1089 Split from C, E & S Africa population in WPE4 by mistake. Terminated based on decision of AEWA MOP6
- P1090 Added as a new population in WPE3. Separated into Coastal Southern Africa (excluding Madagascar) and Central & Eastern Africa populations in WPE4 by mistake. Reactivated in CSR7.
- S9098 European breeding population 25,050 28,250 pairs (BirdLife International 2015). Otherwise, see CSR6.
- S8976 Current total 17,963-28,059 pairs excluding the uncertain estimates for UA. See CSR6 for further explanation.
- S8404 Jennings (2010) estimates numbers only at 28,000 pairs in Arabia. Shobrak (2003) accounts for further 150-200 pairs from EG and SO, but Dodman (2014) reports at least 165 pairs from EG alone. Del Hoyo (1996) mentions 50-100 pairs in KE. Semere et al. (2008) reports 1,067 pairs from ER. This yields an estimate of 29,267-29,367 pairs, which is much less than the 50,000-100,000 pairs estimate of Del Hoyo et al. (1996). The upper limit of the estimate accounts for some unknown numbers from IR, PK and SO.
- T6403 Shobrak (2003, 2013)
- S8934 Jennings (2010) increased the estimates Arabia to 8,000 pairs, discovery of 5,900 pairs in ER (Semere et al. 2008) justifies increasing the estimate. Shobrak (2003) accounts for further 2,100-3,900 pairs from SD, DJ and SO. Habib (2017) reports 2,672 nests from EG. This results in a total of 18,672-20,472 pairs.
- T7229 In the long-term, the population was considered to be stable by Rose & Scott (1994), but no recent trend information is available
- S8959 21,567-21,977 pairs in European breeding countries. North Africa: c. 150-250 pairs (Dodman, 2014). This yields a total estimate of 21,722-22,227 pairs.
- T7032 Long-term trend: strong increase.
 S8957 452,653-630,527 pairs in AT, BE, BY, CH, DE, DK, EE, FI, FR, HU, IE, IS, LT, LV, NL, NO, PL, RU (25%), SE, SJ, SK & UK.
- T7030 Trends based on both the breeding and non-breeding numbers indicate that the population has increased in the long-term and stable/fluctuating in the short one.
- S8958 New estimates for European RU (75%) is 187,500-450,000 pairs, i.e. 562,000-1,350,000 individuals (Mischenko, 2004). Size of the Asian part of the population is unknown.
- T7031 Stable trend is assumed for the breeding population in European RU (BirdLife International 2015). The IWC trend analysis indicate an increase (Wetlands International 2017).
- T7034 Although it is possibly declining in the short-term, it has increased strongly in the long-term.
- P939 Sometimes treated as subspecies of argentatus or a distinct species, Larus heuglini. Includes "taimyrensis" in W Taymyr. In WPE 2 considered as 2 populations of Larus argentatus, L.a. heuglini & L.a. taimyrensis. In WPE 1 considered as 2 populations of Larus cachinnans, L.c. heuglini & L.c. taimyrensis
- P940 Population added in WPE3. Sometimes considered a distinct species, Larus heuglini (barabensis).
- S8969 17,812-26,838 pairs.
- T7043 Significant long-term decline
- S8970 186,382-198,877 pairs. Data from FO is from 1981.
- T7044 Long-term trend is still increasing.
- P1080 Until WPE4, included within fuscus and graellsi
- S8971 188,599-233,084 pairs in BE, DE, DK, NL, NO, SE,
- P1066 Populations in Germany divided into appropriate subspecies in CSR5 (Johannes Wahl in litt. 2008.). However, this has proven untraceable and therefore allocation of countries to populations follows Olsen and Larsson (2010) even if some overlap and intergradation exists. From WPE3 onwards, includes the yellow-legged form referred to as L. a. omissus by some authors.
- S8965 447,705-545,905 pairs in RU, BY, DE, DK, EE, FI, LT, LV, NO, PL, SE and SJ. Country allocation follows Olsen (2010) although intergradation is recognised
- T7039 Declined at an annual rate of 0.5% both in the short- and the long-term. In the long-term, the population has declined only in FI (7-18%) and SE (70-76%), but these support about 14% of the population, which is not seem to be compensated by strong increases in other countries.
- P1067 Populations in Germany divided into appropriate subspecies in CSR5 (Johannes Wahl in litt. 2008.). However, this has proven untraceable and therefore allocation of countries to populations follows Olsen and Larsson (2010) even if some overlap and intergradation exists. UK population erroneously omitted from 3rd and 4th editions.
- \$8966 236,911-262,601 pairs in GL, IS, IE, UK, NL, BE and FR. Allocation of countries to populations follows Olsen (2010).
- T7040 Declined both in the short- and the long-term.
- \$8933 19,000-29,000 pairs in AM, GE and TR (BirdLife International, 2015). Sheldon (2017) reports 530 pairs from IR. This yields a new estimate of 59,000-89,000 individuals.
- T6985 Reportedly, the European population undergoes a continuous decline (BirdLife International 2015) and the site where the species has been recorded breeding in Iran has decreased greatly in size, the global population is thought to be declining at moderately rapid rate approaching 30% in three generations (BirdLife International 2017).
- P1076 Now treated by BOU as a separate species Larus michahellis.
- S8968 400,397-515,868 pairs in Europe. Olsen & Larsson accounts for c. 10,000 pairs from the southern and eastern Mediterranean.
- T7042 Stable in the short-term, increased in the long-term.
- S8967 54,051-87,487 pairs in Europe (BirdLife International 2015). Robust population estimates for C Asia are lacking (Sheldon 2017).
- T7041 Increasing in most European countries, but trend in C Asia is unknown.
- S8964 50,000-100,000 pairs on Greenland.
- T7038 Assumed to be stable both in the short- and the long-term.
- S8962 6,500-20,000 pairs on SJ and N RU.
 T7036 Both the short and long-term trends are unknown (BirdLife International 2015). Although, little is known about the trend in the total Svalbard population, the population on Bjørnøya and Hopen has declined since 1986 (Norwegian Polar Institute 2017). Peteresen et al. (2014) estimated the trend of the larger Russian population as stable or increasing.
- P1061 Population first included in WPE3
- S8963 40,000-115,000 pairs on Greenland and Iceland (BirdLife International, 2015), 50,000-100,000 breeding birds in Canada (Canadian Wildlife Service 2015), Petersen et al. (2014)

- P1043 Population formerly named E Atlantic bre (WPE1) and Northeastern Atlantic bre (WPE2, 3 and 4)
- S8960 113,400-125,976 pairs in DE, DK, EE, ES, FI, FO, FR, IS, NL, NO, RU, SE, SJ and the UK.
- T7033 Declining in the short-term, stable in the long-term.
 S8250 The overall population estimate for this species is of 18,223,468 18,227,968 individuals.
- T6250 New data inadequate to revise trend. There has been no recent overview of the subspecies in the western Indian Ocean since Feare et al. [13] who estimated some populations to be increasing while others decreased, in numbers, but most trends remain unknown.
- T6748 Banc d'Arguin: >210 in 1997, >180 in 1998 & >182 in 2004. Significant past declines at Banc d'Arguin, however.
- \$8248 Revised estimate is based on improved data from Eritrea, Arabia and Iran.
- T6248 Iranian population appears to be stable or slightly increasing during the period of 2003 and 2012, but no trend data is available from the rest of the range.
- P1237 Separated into albifrons, Europe north of Mediterranean (bre) and albifrons, West Mediterranean/West Africa populations in WPE5.
- \$8990 22,788-35,175 pairs in Europe (BirdLife International 2015). According to Dodman (2014) 3,800 pairs in EG.
- T7073 Declining both in the short- and the long-term, but at a slower rate than the threshold for significant long-term decline.
 P1239 Race innominate subsumed within nominate (HBW Alive 2017).
- P2436 In WPE4 this population belonged to one single population, albifrons, Eastern Atlantic (bre). This population was proposed in CSR5 on recommendation of Italy, 2 April 2008, first included in WPE5.
- \$8992 6.378-8.302 pairs in FI, SE, EE, LT, LV, PL, DE, DK, NL, BE, UK, IE, 70% FR (European Topic Centre on Biological Diversity, in prep.)
- T7204 Stable in the short-term, moderate decline in the long-term.
- P2437 In WPE4 this population belonged to one single population, albifrons, Eastern Atlantic (bre). This population was proposed in CSR5 on recommendation of Italy, 2 April 2008, first included in WPE5.
- S8991 7,026-9,381 pairs in ES, PT, IT, FR (30%), SI, HR, HU and SK (BirdLife International 2015). 700-800 pairs in NW Africa (Dodman, 2014).
- T7074 Decline indicated, but not quantified, only in ES. Increase in SI, stable or fluctuating elsewhere except IT, where short-term trend is unknown. However, it decreased by 40-60% IT in the long-term.
- \$8444 Jennings (2010) estimated the total breeding population in Arabia at 4,000 pairs. Berhouzi-Rad (2013) reported only 3 pairs from IR. According to Dodman (2014) c. 20 pairs in EG.
- T6441 No clear evidence of decline during the ABBA survey period despite shoreline development and increasing predation by feral dogs and cats (Jennings, 2010).
- T7230 Number of colonies decreased due to recreational pressures and construction at its breeding grounds (Wanless et al., in prep.). van Roomen et al. (2015) also confirms the decline both for the short- and the long-term based on IWC counts. The species is possibly in significant long-term decline (Angel et al., 2014).
- P1137 Often placed in monotypic genus Gelochelidon.
- S8978 7,852-8,876 pairs in Europe (BirdLife International 2015). According to Dodman (2014) 4500-12,000 pairs in NW and W Africa.
- T7056 Stable/fluctuating both in the short- and the long-term.
- \$8979 8,725-12,336 pairs. (All birds from RU allocated to this population).
- T7057 Significant long-term decline.
- S8429 Estimate is based on Perennou et al. (1994) and there is insufficient information to improve on the estimate. On average, 1,600 individuals were counted on mid-winter counts in IR between 2004 and 2007. Average count total in SA was 664 individuals between 1992 and 1995, but only 143 along the Gulf and 218 along the 7% of the Red Sea coast was counted in Jan. 2014 (Nagy et al., in prep.). 558 at Bar al Hikman in Dec. 2013 (De Fouw in litt, 2014). Little information is available about breeding numbers. The entire population for European RU is 2,000-5,000 pairs, but that partly breeds along the Black Sea (BirdLife International, 2004). It is a common breeder in KZ (Gavrilov & Gavrilov, 2005). No more than 1,000 pairs in Arabia (Jennings 2010).
- P1148 Often assigned to monotypic genus Hydroprogne.
- S8980 Although the population size was revised based on breeding numbers from Wanless et al. (2014) in CSR6, the IWC count totals in 2013 reached 1,962 individuals (Wetlands International 2017).
- T7059 Strong increase in the long-term.
- S8596 46,448 individuals counted in January, rounded to 50,000 (van Roomen et al. 2014).
- T7060 Long-term trend is assessed as stable with TRIM and supports Dodman's (2014) assessment. However, van Roomen et al. (2015) assessed the trend as increasing noting the influence of two high counts towards the end of the assessment period.
- P1157 Separated into caspia, Baltic (bre) and caspia, Black Sea (bre) populations in WPE5. In CSR5 species expert recommends division because thousands of ring recoveries indicate complete separation of Baltic and Black Sea populations in breeding season.
- \$8430 The estimate of Scott (2002) is based on number in the Volga delta. However, there are 50-250 pairs alo in AZ. The species is also a common, at places rare, breeding migrant in KZ (Gavrilov & Gavrilov, 2005). Sklyarenko et al. (2008) adopted a a 1% threshold of 250 individuals, which is equivalent to 25,000 individuals. Jennings (2010) has estimated the breeding population in the order of 500 pairs in Arabia, Shobrak (2003) also mentions 250-350 pairs from EG.
- T7061 Statistically significant strong increase in the long-term. Short-term is uncertain but still has an increasing tendency.
- P2434 In WPE4 this population belonged to one single population, Baltic & Black Seas, Turkey. In CSR5 species expert recommends division because thousands of ring recoveries indicate complete separation of Baltic and Black Sea populations in breeding season.
- S8981 1,650-2,051 pairs in FI, SE, EE & DE.
- T7062 Increased in the short-term, declined in the long-term but at a lower rate than what would qualify as significant long-term decline.
- P2435 In WPE4 this population belonged to one single population, Baltic & Black Seas, Turkey. In CSR5 species expert recommends division because thousands of ring recoveries indicate complete separation of Baltic and Black Sea populations in breeding season.
- S8982 1,100-2,500 pairs in TR and UA.
- T7063 Stable in the short-term but suffered significant long-term decline.
- \$8993 10,294-11,346 pairs in DE, ES, FR, IT and PT (BirdLife International 2015). 200-250 pairs in NW Africa (Dodman, 2014).
- T7075 Increased both in the long- and the short-term.
- \$8994 53,040-86,299 pairs.
- T7076 Increased both in the long- and the short-term.
- S8447 Perennou et al. (1994)
- P1280 sclateri is synonymous with delalandii.
- T7205 The reporting rate has increased between SABAP1 and SABAP2 in 56% of the quarter degree grid cells where the species was observed in S Africa.
- S9143 66,587-173,323 pairs in Europe (BirdLife International (2015). Size of the population breeding in Central Asia is unknown (Sheldon 2017). However, Dodman (2006) estimated the size of the population at 2,500,000-3,500,000 individuals based on observations of high counts in Africa.
- T7077 9 out of 14 European countries reported fluctuating numbers nationally. DE, LT, LV reported increasing numbers and the trend is unknown in BG and RO (BirdLife International 2015). Trend at the wintering areas appear to be a steep decline, but this is probably the result of earlier departure from the South African wintering grounds (Wetlands International 2017).
- S8995 New estimate for European population is 74,359-153,942 pairs (BirdLife International 2015). This numbers correspond well with the numbers of moulting birds counted at the ljselmeer and Sivash (250,000-420,000 individuals - van der Winden 2002), but these figures do not include birds from C&W Asia which probably use other moulting sites. Assuming similar densities for the Asian part of the range of the population, van der Winden (2008) estimated 38,000-78,000 breeding pairs there. Using a conversion factor of 2.5, after rounding this results in a new estimate of 280.000.580.000 individuals.
- T7078 The EU population has declined by 25% in 3 generations (BirdLife International 2015), but the trend of the European population is unknown because of lack of trend data for nine countries including RU and the whole of C&W Asia. Declining trend is also shown at the liselmeer stopover site for the period of 1980-2007 (van der Winden, 2008). Significant long-term
- P1189 In CSR7, merged with the Madagascar part of the former arideensis, Madagascar, Seychelles & Mascarenes population following the revised taxonomy in HBW Alive and following Safford and Hawkins (2013) who recognise arideensis only from Seychelles, St Brandon and Rodrigues and treat birds from Madagascar as nominate race following Tree (2005).
- P1192 Perhaps better assigned to bangsi (del Hoyo et al. (1996)).
- S8635 Tz: 850-1300 pairs, Kenya & Somalia 3K-5K pairs T7206 - No information is available on recent trends
- \$8986 2,268-2,882 pairs
- T7208 Increased both in the short- and the long-term (i.e. between 2000-2012 and 1980-2012 respectively). However, it has decreased drastically from its likely peak of perhaps 3,500 pairs in Britain and Ireland in the late 1950s and early 1960s (Newbery, 1999) and which period still within 7.5 generation lengths (GL: 10.2 years for this species following BirdLife International
- P1194 Races arideensis, korustes and bangsi synonymized with gracilis based on genetic study (HBW Alive, 2017). The Madagascar part of this population was merged with dougallii, Southern African population in CSR7.
- P1195 Races arideensis, korustes and bangsi synonymized with gracilis based on genetic study (HBW Alive, 2017)
- \$8210 Jennings (2010) estimates that the total breeding population in any one year could be not more than 40-50 pairs
- T6213 Jennings (2010) notes that, although breeding numbers at each site vary from year to year, there is an overall marked decline since 1980.
- P2466 This population was created in CSR7 by merging the dougallii, Southern African population with the Madagascar part of the former arideensis, Madagascar, Seychelles &
 Mascarenes population following the revised taxonomy in HBW Alive and following Safford and Hawkins (2013) who recognise arideensis only from Seychelles, St Brandon and Rodrigues and treat birds from Madagascar as nominate race following Tree (2005).
- S9100 Data combined from Dodman (2014)
- T7207 No recent trend information is available

- S8988 255,313-527,836 pairs in NO, SE, FI, EE, LT, LV, PL, DK, CZ, SK, AT, HU, SI, RO, BG, GR, UA, TR, RU and CY (BirdLife International 2015). 270 pairs at Port Said, Egypt (Habib in litt. 2014)
- T7210 The population has slightly increased both in the short- and the long-term.
- S8987 57,232 72,103 breeding paisr in IE, UK, DE, NL, FR, CH, ES, PT, ESIC, PTAC, PTMA and IT (BirdLife International 2015). According to Dodman (2014) 100-300 pairs in NW Africa.
- T7071 The short-term trend is stable with a negative tendency (0.9871-1.0013). Increase in the long-term (1.0061 1.0068)
- \$8702 Jennings (2010) accounts for 64,100-95,100 pairs in Arabia, Behrouzi-Rad (2013) and Tayafeh (2013) for 2000-2500 individuals in IR, Dodman (2014) for 25,560-36,580 pairs in
- T6442 Lot of islands were lost in Arabia, but birds probably moved to other islands (Jennings 2010). Shobrak et al. (2013) noted increase in the SA Red Sea. Decline in IR based on comparison of count data from Behrouzi-Rad (2013) and Tayafeh et al. (2013).
- P1219 In WPE2 this population belonged to one single population (Arctic (bre)/S Oceans (win)).
- \$8989 564,000 906,000 pairs in Europe (BirdLife International 2015). 100,000-200,000 breeding birds in CD (Canadian Wildlife Service 2015). Similar numbers are assumed for the rest of the range in RU.

 T7072 - Unknown status in Canada and W Siberia
- P1168 Sometimes assigned to emigrata or torresii
- \$8706 1,929-2,264 pairs in Libya between 2006 and 2010.
- T7064 Little variation in size of Libyan breeding population between 2006 and 2010.
- P1169 Sometimes assigned to bengalensis or arabica.
- \$8431 \$A: 2,000-4,000, YE: 1,000-5,000, DJ: 1,000, EG: 1,500-4000, \$O: 0-500, ER: 63,000 pairs (Coulthard, 2001, PESGRA, 2003, De Marchi, 2009, Jennings, 2010, Dodman, 2014).
- \$8432 64,750-74,750 pairs in Arabia (Jennings, 2010). Further 27,554-30,799 in IR (Tayefeh, 2013).
- T6430 Based on data from IR, numbers show increase over the last decade (Behrouzi-Rad 2013, Tayafeh 2013).
- S8983 53,311-61,981 pairs.
- T7066 Also long-term increase.
 S8984 20,620-73,760 pairs in UA, RO, BG, GR, TR and RU.
- T7067 Fluctuating in RU and UA, the two largest population.
- S8985 See CSR6.
- \$8708 85,000-105,000 pairs.
- T6747 A decrease in the numbers of Royal Terns in 2011 on lle aux Oiseaux, Senegal can partly or completely be explained by an increase on other islands.
- P1172 In WPE2 this population belonged to one single population (S Africa/Madagascar (breeding)).
- \$8707 A range seems most appropriate, as breeding population is significantly related to food availability.
- P1173 In WPE2 this population belonged to one single population (\$ Africa/Madagascar (breeding)). Then this population was separated as 'enigma' subspecies. 'Enigma' is now synonymised with the nominate form. However, the population is treated separately until further evidence is available to confirm the degree of exchange of individuals among colonies.
- . T7069 Possibly increasing in the short-term.
- P1174 In CSR6 it was proposed to combine this population with the Madagascar & Mozambique/Southern Africa population. However, the population is treated separately until further evidence is available to confirm the degree of exchange of individuals among colonies.
- P1175 In WPE2 this population belonged to one single population (NE Africa/SW & S Asia).
 \$8433 2,000 pairs in SA, 1,000 in DJ, none in YE (Jennings, 2010). 2,200 pairs in ER (Semere et al., 2008). Up to 1,000 pairs in SO, 152 in EG, 370 in SD (Shobrak, 2003). Dodman (2014) updated figure for EG to 300 pairs.
- P2451 Proposed as a new population for CSR6, combining the Madagascar & Mozambique/Southern Africa and Eastern Africa & Seychelles populations, but returned to 2 distinct populations in CSR7 with different subspecies
- S8213 Lack of good data
- T7211 European population is stable (SE), fluctuating (FI) or mostly unknown. Apparently, it also fluctuates in the long-term.
- S8212 Population estimates mainly based on means or in some areas more or less exact counts
- T7212 Declining in the short-term, increased in the long-term. It is increasing everywhere but Iceland where it declined by 30-50%, FO and SJ where unknown. The long-term increase is mainly driven by the large increase in the UK.
- T6228 Fluctuating in Russia, unknown in Norway & Bear Island.
- S8226 Population estimates mainly based on means or in some areas more or less exact counts.
- S8227 Population estimates mainly based on means or in some areas more or less exact counts. Earlier figure of 13,500,000 was erroneous.
- T7213 Although the short-term population trend would be positive if calculated based on the data reported to BirdLife International (2015). However, Harris and Wanless (2011) suggests that it has undergone declines or probable declines since 2000 in the UK that holds about half of this population. JNCC (2017) provides evidence of declining productivity and return rates since 1986. Declines are also reported from FO and S NO.
- \$9102 BirdLife International (2015) reported 26,896-39,840 pairs in EE, FI and SE from the period of 2006-2012 allocating the SE population proportionally as in Berglund & Hentati-Sundberg (2014). However, the figures reported by Berglund & Hentati-Sundberg (2014) are retained because their report covers a more recent period.
- T7214 Steep (>9% p.a.) decline in the short-term, less rapid, but still significant (>1.6% p.a.) long-term decline.
- S9103 Berglund and Hentati-Sundberg (2014) reported 122,000-134,000 pairs from CD, GL, SJ and RU. BirdLife International (2015) has reported 45,263-86,316 breeding pairs from GL, SJ and European RU only. The former estimate is being used because of being more comprehensive. • T7215 - Berglund & Hentati-Sundberg (2014) reported unknown trend. BirdLife International (2015) has reported stable trend for GL, unknown for SJ and RU.
- S9104 The estimate is based on Berglund & Hentati-Sundberg (2014). BirdLife International (2015) reported 211,088-590,711 pairs that is equivalent to 633,000-1,772,000 individuals for DK, part of GL, IE, NO, part of SE and the UK. The difference is mainly caused by the much higher estimate for GL.
- T7216 A mix of unknown, increase and stable trends at local level. Based on data from BirdLife International (2015), the overall trend appears to be stable. S9105 - New population size is calculated based on population estimate from 1990-2000 reported by BirdLife International (2015) reduced proportionally by the percentage decline figures given for the short-term in response to comments from IS.
- T7217 10-29% decline between 2000-2010, 35-50% decline between 1980-2010.
- S9111 Population estimates based on means
- S9106 Berglund & Hentati-Sundberg (2014) estimated the population size at 460,000 pairs based on data from the period of 1998-2013, while BirdLife International (2015) has estimated around 851,130 pairs based on data from the period of 1987-2012. The main difference concerns IS where the population size estimated by the latter is twice of the former
- T7222 Declining both in the short- and the long-term. Rate of decline in the short-term is very steep
- S9107 Berglund & Hentati-Sundberg (2014) estimated the population 64,000-70,000 pairs including Canada. BirdLife International (2015) estimated for Europe only 128,102-164,720 pairs. The more recent, specialist estimate is retained here.
- T6221 Increasing/stable in most areas, but unknown for prominent areas like Norway and Greenland.
- T7221 Only increasing in Canada at a rate of 1% p.a., trend unknown in RU, decreasing everywhere else.
 P1320 Following CSR6, this population has been split into the 'E North America, Greenland/NW Atlantic' and the 'Iceland, Faeroes, Scotland, S Norway, Baltic/NE Atlantic' populations.
- S9108 Berglund and Hentati-Sundberg (2014) estimated the population at c. 265,000 pairs, but allocated only the birds from Scotland to albionis but this differs from the treatment of the species in the UK. Therefore, the population estimate is updated based on data from BirdLife International (2015), i.e. 157,057-157,039 pairs.
- T7218 Increase in British Isles both in the short- and the long-term
- S9110 148,129 pairs estimated for NO (Fauchald et al. 2015), 6,000-12,000 for RU (BirdLife International et al. 2015). T7220 - The NO population has apparently increased.
- P2460 After CSR6, this population has been split from the former 'aalge, E North America, Greenland, Iceland, Faeroes, Scotland, S Norway, Baltic' population.
- S9109 2,017,584-2,718,364 pairs (BirdLife International 2015) • T7219 - Declined at the rate of c. 2.5% p.a. between 2000-2012 (if the UK reporting for a different period - 1998-2002 - excluded), increased at a rate of c. 1.2% between 1980-2012. During this period, it has not been reported to increase in any of the range states by BirdLife International (2015).
